A FUZZY LOGIC BASED FRAMEWORK FOR

RELEVANT INFORMATION RETRIEVAL

THESIS

submitted in fulfilment of the requirement of the degree of

DOCTOR OF PHILOSOPHY

to

YMCA UNIVERSITY OF SCIENCE & TECHNOLOGY

by

MAMTA KATHURIA Registration No: YMCAUST/PH53/2011

Under the Supervision of

Dr. C. K. NAGPAL

Professor

Dr. NEELAM DUHAN

Assistant Professor

Department of Computer Engineering Faculty of Engineering and Technology YMCA University of Science & Technology Sector-6, Mathura Road, Faridabad, Haryana, INDIA November 2018

DEDICATION

to

My Husband Mr. Naresh Kathuria

and

My beloved kids Parth Kathuria & Yuva Krishna

CANDIDATE'S DECLARATION

I hereby declare that this thesis entitled "A FUZZY LOGIC BASED FRAMEWORK FOR RELEVANT INFORMATION RETRIEVAL" by MAMTA KATHURIA, being submitted in fulfilmentof requirement for the award of Degree of Doctor of Philosophy in the Department of Computer Engineering under Faculty of Engineering and Technology of YMCA University of Science and Technology, Faridabad, during the academic year 2018-2019, is a bonafide record of my original work carried out under the guidance and supervision of Dr. C. K. NAGPAL, PROFESSOR & Dr. NEELAM DUHAN, ASSISTANT PROFESSOR, DEPARTMENT OF COMPUTER ENGINEERING and has not been presented elsewhere.

I further declare that the thesis does not contain any part of any work which has been submitted for the award of any degree either in this university or in any other university.

(MAMTA KATHURIA)

Registration No. YMCAUST/PH53/2011

CERTIFICATE

This is to certify that this thesis entitled "A FUZZY LOGIC BASED FRAMEWORK FOR RELEVANT INFORMATION RETRIEVAL" by MAMTA KATHURIA submitted in fulfilment of the requirement for the award of Degree of Doctor of Philosophy in DEPARTMENT OF COMPUTER ENGINEERING, under Faculty of Engineering and Technology of YMCA University of Science and Technology, Faridabad, during the academic year 2018-2019, is a bonafide record of work carried out under my guidance and supervision.

I further declare that to the best of my knowledge, the thesis does not contain any part of any work which has been submitted for the award of any degree either in this university or in any other university.

> Dr. C. K. Nagpal **PROFESSOR** Department of Computer Engineering Faculty of Engineering and Technology YMCAUST, Faridabad

Dr. Neelam Duhan ASSISTANT PROFESSOR Department of Computer Engineering Faculty of Engineering and Technology YMCAUST, Faridabad

Date:

ACKNOWLEDGEMENT

It gives me immense pleasure to acknowledge the people whose priceless contributions helped me reach here. Without their support, this piece of academic work, in the form of my doctoral thesis, would have just been reduced to mere ink on paper. First and foremost, my deepest and heartfelt thanks to Dr. C. K. Nagpal who has been not just a guide par excellence but also an inspiring teacher, Nagpal sir not only created a solid foundation in my mind , but also nurtured it over the years till this day through his tireless efforts.

Sir, you have shown me the right path always, lit the lamp of clarity whenever I was in doubt, corrected me when I was wrong, encouraged me when I was right, criticized me when I became over-confident and motivated me whenever I would lose hope.

I express my deep sense of gratitude to Dr. Neelam Duhan, for her valuable guidance and help without which it was not possible for me to complete my work. Mam, you believed in my abilities and gave unconditional support to help me achieve excellence throughout my research work culminating in this doctoral thesis.

It is my firm belief that no success in life can ever be achieved without the well wishes and support of one's family. And when I look back from where I have reached today, my belief only becomes stronger. First and foremost, my very special remembrance and gratitude towards my father, Sh. Subhash Mehta, for believing in me and giving me the best lesson of life. My father inspired me to do better with every passing day. I am sure no one today would be as proud as him seeing me complete my doctoral thesis. I also heartily thank my dearest mother, Mrs. Kamlesh Rani, Father- in- law Sh. Roop Chand and mother- in- law Mrs. Kaushalya, Brothers Prayag and Anand, Sister Neha for their unwavering support. And even though my sons Parth Kathuria and Yuva Krishna are too young to understand these words, thanks to them for bringing smiles on my face by coming into our lives.

People say that behind every successful man there is a woman, but in my case it has been the other way round. No matter what I write, no words can even suffice my gratefulness for the man of my life, my best friend, my biggest support, a neverending source of inspiration and righteousness, my soul mate and life partner Mr. Naresh Kathuria. He gave me hope, courage and the reason to be what I am today, my true self and he always said, "Be the best at what you do". Today, I know I am making him proud.

I would like to express my sincere gratitude to chairpersons Dr. Atul Mishra and Dr. Komal Kumar Bhatia for their valuable advice, support and information on different aspects.

I would also like to thank to my colleagues Dr. Shilpa and Ms. Amita, my dearest friend Ms. Deepshika, my fellow students Anuradha, Riya and Kalyan Mudireddy for all the help, discussion and great company.

And finally, thinking that one entity without whose grace, all the above wonderful people wouldn't have come in to my life and without whose blessings, I wouldn't have been where I am. Thank you almighty, the ever knowing, omnipresent and ever-forgiving God for being kind and watching over me all these years and I know that you will continue to do so forever.

ABSTRACT

The performance of search engines in today's scenario is quite impressive yet there has been the ever felt need for novel mechanisms for executing/realizing users' expectations seeking the rich set of relevant results for the query submitted by them. The massive size, continuous update of the information, heterogeneity on the basis of various factors like linguistics, geographical location, cultures and other parameters make the task of information retrieval quite complex and challenging.

Most of the web search engines are based upon the query text which is a very short piece of natural language expression. The ambiguity in the natural language, conceptual references, entity references and synonyms thereof add the complexity to the matter. To ensure the rich and relevant results in response to submitted query, which is a very short piece of text, it is desirable that search engine must be able to rephrase/expand the query through its multiple versions with each version containing the quality synonym for the entity and the attribute references. The search engine must also be in a position to translate a given concept to its appropriate set of instances using worldly knowledge.

The work carried out in this thesis involves generating synonyms of the attribute word present in the query through the identification of their contexts. The synonyms so identified have the global implications based upon the billions of pages instead of individual perception. The methodology used not only creates the synonyms but also provides an index to assess the similarity in meaning. The index was normalized and a fuzzy rule base was created for the purpose of usage in automation process.

The work also involves the creation of set of synonyms for the entity references. In contrast to the attribute words, there doesn't exist any lexical reference to find the seed for entity synonym. The proposed work is based upon the web data and web logs containing rich set of information. This work is an improvement over the existing works both in terms of quality and quantity. This has been proved through the generation of an index that measures the similarity between two entity synonyms.

The work was further extended to realization of the conceptual references to their appropriate instances through the use of latest available worldly knowledge

repository, PROBASE, in the light of user centric data such as browsing history, geographical location, IP address etc.

The work explores the alternative representations for *attributes, entity references* and *concepts* components of a query. *Keywords* which carry the essence of the query were not considered for alternative representation. The alternative representations proposed in this work shall help the search engines in meaningful rephrasing of the query to ensure rich and relevant information as sought by the user.

CHAPTER I INTRODUCTION

1.1 SEARCH ENGINES & INFORMATION RETRIEVAL

The World Wide Web (WWW) is a gigantic repository that keeps information related to almost every domain of knowledge accessible everywhere on anytime basis. The massive size, continuous update of the information, heterogeneity on the basis of various factors like linguistics, geographical location, cultures and other parameters make the task of information retrieval quite complex and challenging.

Though the performance of search engines in today's scenario is quite impressive yet there has been the ever felt need for novel mechanisms for accomplishing expectations of the users who are seeking the rich set of relevant results for their submitted queries.

The basic reasons for the inability of the search engines to provide the relevant results which are not up to expected levels are as follows:

- Query is a very short piece of text in natural language and successful retrieval is very much dependent of the intent of the user behind the query.
- Natural language is ambiguous and affects the relevance/quality of search results returned by the search engine.
- Users may use slang terms which are not as such part of the language.
- The reference in the query may be conceptual requiring proper instantiation.
- The reference in the query may refer to an entity recognizable by different names.
- Current Lexical resources are unable to cover the heterogeneity of the web.
- Web is continuously updating.

All these issues need to be addressed for getting the rich and relevant information from the web. The literature contains a lot of work in this regard, the study of which motivated us to carry out the work proposed in this thesis.

1.2 PROBLEM IDENTIFICATION

To understand the ongoing work being carried out to overcome the above mentioned problems, nearly 100 research papers, as listed in the reference section and discussed in brief in Chapter II of this thesis, were studied. It was felt that there is an ample opportunity to carry out further research work to ensure the rich and relevant information by working on the various components of the query. The literature survey has shown that the basic constituents of a query can be classified into four categories: *Keywords, Attributes, Entities and Concepts*.

- *Keywords* are non-trivial words which carry the essence of the query. The keywords make the query meaningful and are the major guiding factors for relevant information retrieval to be carried out by the search engines.
- (ii) Entities are persons/places/objects referred in the query which have distinct and independent existence. Different users may refer to the same entity in different manners. For example, the newspaper The Times of India may also be referred to as TOI. A search engine must be able to handle these multiple versions of the references used in the query. These multiple references have been referred to as entity synonyms in the work [1, 2]. Creation of appropriate set of entity synonyms for a given entity is also a major requirement for relevant and rich information retrieval. Various contributions in this field are available in [1-9].
- (iii) Attributes are the words which define the features/ characteristics of entities and keywords used in the query. To enrich the search process, a web search engine may create multiple versions of the same query by using the appropriate set of synonyms of the attributes used in the query and create an index to access the quality of the synonym generated. Various contributions in this field are available in [10-18].
- (iv) A Concept in the query is a word which refers to a broad category of objects in generic manner. For example, in the query "good actors in India" Good actors is a concept. A concept referred in query has to be translated to its closest set of instance(s). Handling of the concept is the most challenging task for the search engine as its resolution requires the understanding and usage of worldly knowledge. The instantiation of a

concept can vary depending upon the local & global contexts. The hardest part of the query expansion is to find the appropriate instantiation for the concept used in the query as per the requirement of the user. Various contributions in this field are available in [20-32].

After going through the literature, following inferences were drawn:

- Keywords are the essential part of the query and should not be disturbed/modified/altered.
- Lexical resources are unable to provide the requisite set of synonyms for the words used in the query owing to the widespread and heterogeneous nature of the web. So, there is a need to find out global mechanisms for creating the set of synonyms which truly cover the heterogeneity of the web.
- Alternative references to entities (also known as entity synonyms) are not at all supported by the lexical resources. The only way one can find out the entity synonyms is through web exploration and analysis of web logs.
- Conceptual references need to be translated into their worthy instances which are quite a challenging task as it requires worldly knowledge.

After exploring all this literature, we were in a position to set the objectives of the proposed work.

1.3 PROBLEM DEFINITION

To ensure relevant web search through query rephrasing or expansion using

- rich set of identified synonyms for the entities and the attributes used in the query
- appropriate instances for the concepts present in the query and to devise novel mechanisms for the purpose.

1.4 **OBJECTIVES**

Following objectives were set for the proposed work:

- a) To devise a mechanism to search synonyms of an attribute word of the query using huge document repositories.
- b) To devise a mechanism to search rich set of entity synonyms for an entity using static and dynamic web.
- c) To design an index to assess the quality of synonyms as two synonyms of the same word can't have same intensity.
- d) To devise a mechanism to translate a concept to its intended instances using worldly knowledge source.
- e) To devise a mechanism for automated usage of identified set of synonyms to be utilized by the machine.

1.5 ACCOMPLISHMENTS

Following accomplishments were made during this work:

- a) A mechanism to search synonyms of an attribute word on the basis of the context identification using multiple corpora was proposed and implemented. The method is quite an improvement over the existing methods which use page count and snippets.
- b) A mechanism to generate rich set of entity synonyms for an entity using query log and anchor text was proposed and implemented.
- c) For both of the above mechanisms, an index was created to assess the quality of synonyms. The index was fuzzified and a Fuzzy Rule Base (FRB) was created for automated deployment of synonyms for various purposes.
- d) A mechanism to translate a concept to its intended instances was proposed and implemented using PROBASE (the largest available worldly knowledge source) [33].

1.6 ORGANIZATION OF THE THESIS

The thesis has been organized as follows:

Chapter II: Literature Survey: This chapter contains a discussion on the available work related to search engine evolution, semantic similarity between words, entities and concept based web search. Based on the literature survey on each topic, the

problems and challenges have been identified and discussed in brief. These problems and challenges form the basis for the work carried out.

Chapter III: Synonym Resolution for Attribute Component in Query: This chapter talks about the proposed semantic similarity technique and its implementation for attributes component present in the query. To assess extent of similarity between the synonyms under consideration and the candidate word, list of their contexts have been taken into consideration. The work makes use of various corpora for extracting contexts.

Chapter IV: Dynamic Entity Resolution: This chapter covers the detailed discussion on the proposed and implemented work to generate a rich set of entity synonyms for the commonly used entities using web data, web log and anchor text. An index has also been created to assess the quality of the created synonym. Obtained results have been compared with the existing techniques.

Chapter V: Concept Resolution for Focused and Enriched Web Information Retrieval: This chapter proposes and implements an algorithm for concept resolution using PROBASE, a huge taxonomy on worldly knowledge created by Microsoft, in combination with users' statistics resulting in focused and enriched outcomes. The results so obtained have been compared with the outputs of existing search engines such as Google, Bing and Yahoo.

Chapter VI: Conclusion and Future Scope: This chapter concludes the work and provides a description of potential future work in the area under consideration.

We move to next chapter that presents existing literature related to problem taken up in this work.

CHAPTER II LITERATURE SURVEY

2.1 INTRODUCTION

In this chapter, the study of existing work carried out by various researchers to make the information retrieval precise as per the requirement of the web searcher is taken up. The process started with the study of the search engines evolution process from their infancy to the current scenario. For this purpose, many websites and research papers (more than 100) were referred to. The outcome of the study has been shown in Table 2.1.

| Sr. No | Year/Search Engine Name | Key Developer / Developed at or Owner | Features and Innovations | Current Active status/ Alexa Rank |
|-----------|---------------------------------------|---|--|--|
| 1. | 1990 Archie[34] | Alan Emtage, Peter J. Deutsch, Bill McGill University, Montreal | FTP Server based sharing of files crawling concept Script-based data gatherer Regular Expression based matching retrieval of files for user query | Not Active Alexa N.A |
| 2. | 1992 Veronica & Jughead [35] | Fred Barrie, Rhett Jones University of Naveda System Computing Services group | Menu Driven approach Ability to search plain text files Keyword based search in Its own designed Gopher Index System | Not Active Alexa N.A |

2.2 DEFINING THE SCOPE OF THE PROBLEM

The task to be accomplished in this work was to design an efficient framework for relevant information retrieval from the World Wide Web (WWW). The basis of the information retrieval is a query which is a short piece of text and the search engine has to analyze this short piece of text to ensure unambiguous, precise and rich information as per the requirement of the user. Since query is a very short piece of text, selecting an appropriate set of web pages is an uphill task. This led to the need for query recommendation in terms of Expansion/ Rephrasing/ Reformulation of the query that helps search engines in creating multiple versions of the input query, using polysemy and synonymy, to accomplish a rich and relevant information retrieval. These techniques use Query Expansion [82, 83], Association Rules [84], Query-Flow Graph [85] and Query Clustering [86].

To understand the crux of the matter, many papers were studied and we got concrete information in a paper [27,87] which conveyed that contents of the query text can be classified into four major types: *Keywords, Entities, Attributes* and *Concepts* with description as follow:

- (i) *Keywords* are non-trivial words which carry the essence of the query. The keywords make the query meaningful and are the major guiding factors for relevant information retrieval to be carried out by the search engines.
- (ii) *Entities* are persons/places/objects referred in the query which have distinct and independent existence. Different users may refer to the same entity in different manner. For example, the newspaper *The Times of India* may also be referred to as *TOI*. A search engine must be able to handle these multiple versions of the references used in the query. These multiple references have been referred to as *entity synonyms* in the literature. Creation of appropriate set of entity synonyms for a given entity is also a

major requirement for relevant and rich information retrieval. After studying the various contributions in this field we proposed a new strategy in this domain as discussed in Chapter IV of this thesis.

- (iii) Attributes are the words which define the features/ characteristics of entities and keywords used in the query. To enrich the search process, a web search engine may create multiple versions of the same query by using the appropriate set of synonyms of the attributes used in the query. This necessitates the creation of the appropriate set of synonyms for a given attribute and to create an index to access the quality of the synonym generated. After studying the various contributions in this field we proposed a new approach in this domain as discussed in Chapter III of this thesis.
- (iv) A Concept in the query is a word which refers to a broad category of objects in generic manner. For example, in the query "good actors in India", Good actors is a concept. A concept referred in query has to be translated to its closest set of instance(s). Handling of the concept is the most challenging task for the search engine as its resolution requires the understanding and usage of worldly knowledge. The instantiation of a concept can vary depending upon the local and global contexts. The hardest part of the query expansion is to find the appropriate instantiation for the concept used in the query as per the requirement of the user. After studying the various contributions in this field we proposed a new strategy in this domain as discussed in Chapter V of this thesis.

Our work in this thesis concentrates upon the query expansion and resolution process by using appropriate set of synonyms for attributes & entities and appropriate set of instances for concept resolution. Since different synonyms created for an input entity/attribute may not have same extent of similarity with the input entity/attribute, therefore, an index for assessing this extent of similarity was created which was fuzzified after normalization process. This fuzzification helped us in creating a Fuzzy Rule Base (FRB) which can be used for automated usage in the web search process. All this work leads to the creation of a framework for rich and relevant information retrieval from the web.

2.3 LITERATURE SURVEY FOR ATTRIBUTE SEMANTIC SIMILARITY

The inadequacy of the manually created lexical resources has been long felt due to their inability to cater various diversified domains of knowledge area such as engineering, medical, music and finance etc. Moreover, mostly their updation is also based upon the perception of a few people without much usage of statistics and engineering. With the growth of web over multifaceted heterogeneous environment spread over variety of domains, people, nationalities, dialects etc., the realization has become more and more prominent wherein these resources are unable to provide the requisite support to the web search engines for the purpose of meaningful query expansion. Thus, with the exponential growth of web, the need for meaningful query expansion has gained more and more prominence. This issue can only be addressed through proper semantic resolution which in turn requires knowledge about exact estimate of the semantic similarity between the terms. The growth of the web has pushed the research in the area of precise semantic similarity measurement to help target web users in getting the accurate results through proper semantic interpretation of their queries.

Major contributions in this field are as follows:

- (a) Pilehvar, Jurgens, & Navigli (2013)[88] presented a unified approach for semantic similarity finding that operates at multiple levels from comparing word senses to comparing text documents. The method leverages a common probabilistic representation over word senses in order to compare different types of linguistic data. This unified representation shows state-of-the-art performance on three tasks: semantic textual similarity, word semantic textual similarity and word sense coarsening.
- (b) Severyn, Nicosia, & Mchitti (2013)[89] have taken up the task of (STS) using a large number of pair-wise similarity features. Their model includes: encoding of input texts into relational syntactic structures, use of tree kernels to handle feature engineering, combining both structural and feature vector representations in a single scoring model using Support Vector Regression (SVR). The contribution of the work is quite significant in the area of semantic textual similarity.

- (c) Specia, Jauhar & Mihalcea (2012)[90] provided a mechanism for Lexical Simplification which involves the replacement of words and phrases through their simpler variants using complexity analysis, substitute lookup and context-based ranking.
- (d) Jurgens, Mohammad, Turney & Holyoak (2012)[91]have focussed on relational similarity such as entity:sound (dog:bark, cat:meow), cause:effect (virus:flu) etc. for the purpose of semantic similarity resolution.

Above mentioned approaches were quite academic and based upon classical concepts and statistics. The subsequent approaches in semantic similarity resolution involve the use of web contents to find the extent of semantic similarity. The inherent advantage of such an approach is its ability to take into consideration the heterogeneity of the web making them useful for the information retrieval from the web.

Initial efforts to make a decision about semantic similarity based upon web content were based upon page count. In these cases page count of the word pair (say P and Q) is taken into consideration for computation of semantic similarity. Here, H(P) and H(Q) indicate the page counts for word P and Q respectively and H(P \cap Q) denotes the page count for conjunctive query 'P AND Q'. Based upon the page count, various indices have been proposed, which are as follows:

$$WebJaccard(P,Q) = \begin{cases} 0, & \text{if } H(P \cap Q) \le c ,\\ \frac{H(P \cap Q)}{H(P) + H(Q) - (H(P \cap Q))}, & \text{otherwise} \end{cases}$$
(2.1)

This coefficient is set to zero if page count $H(P \cap Q)$ for the conjunctive query is less than a threshold c.

$$WebOverlap(P,Q) = \begin{cases} 0, & \text{if } H(P \cap Q) \le c ,\\ \frac{H(P \cap Q)}{\min (H(P), H(Q))}, & \text{otherwise} \end{cases}$$
(2.2)

$$WebDice(P,Q) = \begin{cases} 0, & if \ H(P \cap Q) \le c ,\\ \frac{2H(P \cap Q)}{H(P) + H(Q)}, \ otherwise \end{cases}$$
(2.3)

The fourth measure WebPMI (Pointwise Mutual Information) reflects the independence between two probabilistic events and is defined as:

$$WebPMI(P,Q) = \begin{cases} 0, & \text{if } H(P \cap Q) \le c ,\\ \log_2 \left(\frac{H(P \cap Q)/N}{H(P)/N} \right), & \text{otherwise} \end{cases}$$
(2.4)

where N is the number of documents being indexed by the search engine. Probabilities are assessed based on maximum likelihood principle.

With the advancement in search engine technology, new empirical methods were defined in the light of search results.

Cilibrasi & Vitanyi (2007)[92] defined a semantic similarity measure based called Normalized Google Distance (NGD) based upon page count provided by the search engine. The NGD measure can be defined as given in (2.5).

$$NGD(P,Q) = \frac{\max\{\log H(P), \log H(Q)\} - \log H(P,Q)}{\log N - \min\{\log H(P), \log H(Q)\}}$$
(2.5)

All these methods consider the co-occurrence of words without taking into account the context of the words in which they occur on the page.

2.3.1 Drawbacks of Page Count Based Measures

The major drawback of all these methods is that in many cases, two words may appear together on some pages even if they are not related, owing to distance between them in the page. Due to this reason, the page count based methods were considered to be quite crude and needed refinement through the augmentation of proper context. Thus, new methods were suggested based upon the text snippets where co-occurrence is taken into account only if it exists within a text snippet making it more relevant. These types of methods are outlined below.

(a) A double-checking model using text snippets was suggested by Chen, Lin & Wei (2006)[93] for measuring semantic similarity between two words. For computing the similarity between words P and Q, occurrences of word P are counted in the snippets for word Q and similarly the occurrences of word Q are counted in the snippets for word P. Then, the corresponding values are used to calculate the similarity between P and Q by using Co-occurrence based Double-Checking (CODC) measure as defined below:

$$CODC(P,Q) = \begin{cases} 0, & \text{if } f(P@Q) = 0, \\ exp\left(log\left[\frac{f(P@Q)}{H(P)} \times \frac{f(Q@P)}{H(Q)}\right]^{\alpha}\right) & \text{, otherwise} \end{cases}$$
(2.6)

where f(P@Q) is the number of occurrences of P in the top ranking snippets of Google corresponding to query Q, H(P) denotes the page count for query P, and α is a constant which was experimentally set to the value 0.15 by the authors. The drawback of the method is its dependency on the ranking method adopted by a search engine in use. It happens because a search engine considers publication date and link structure along with semantic similarity while ranking the search results corresponding to the user query.

- (b) Bollegala, Matsuo, and Ishizuka (2011)[10] proposed an empirical method to measure semantic similarity between two words based on page counts and text snippets retrieved from a search engine in response to the said words. They identified several semantic relations between given words by the using pattern extraction and pattern clustering algorithm. They also used support vector machine based supervised learning model for deciding the appropriate boundaries of classification.
- (c) The work was further extended by Rada, Mili, Bichnell & Blettner (1989)[94] taking into consideration the taxonomy of words. According to them, shorter the path in taxonomy, more similar the words are.
- (d) Resnik (1995)[95] proposed semantic similarity measurement between two concepts using Brown Corpus [96] and WordNet (2005)[97]. The proposed method finds the similarity between the concepts C1 and C2 on the basis of a third concept C that subsumes both the concepts and is the biggest of all such possible contents.

2.3.2 Limitations of Existing Word Similarity Methods

Above mentioned methods have the following drawbacks:

- Mere page count based methods are quite crude
- A text snippet may be quite long
- Word taxonomy may depend upon various heterogeneous aspects

• Processes like concept identification and relation identification are perception dependent

All these drawbacks have been the motivating factors for the proposed work as described in Chapter III.

2.4 LITERATURE SURVEY FOR ENTITY RESOLUTION

An *Entity* refers to a place, person, thing, event or abstraction having a distinct and separate existence from other instances of similar attributes e.g. *The Times of India, The Hindustan Times, Kabhi-Kabhi, Dilwale Dulhaniya Le Jayenge, i20, Santro Xing* etc. An entity may be referred with a list of formal and informal alternative names e.g. *TOI* and *Times of India* refer to the same entity. Similarly, *Tere Bin Laden-2* and *Tere Bin Laden: Dead or Alive* are not different. The references to an entity may be local or global depending upon the context of the underlying domain. These references are normally informal and cannot be resolved using the lexical resources.

Moreover, the alternative references are dependent upon the heterogeneity of the web spread over the various factors such as geographical domain, linguistic domain, education domain, slang terms etc. It is quite possible that a particular slang term or other term may serve as entity synonym for two or more entities e.g. the term *Godfather* when searched on the web may normally refer to the movie *The Godfather* but it is quite possible that it may be referring to *Godfather's Pizza* or *The Godfather Collection*.

Entity synonyms are important ingredients of current web search as major part of the web search is related to movies, events, monuments, books, players, actors etc. To find the appropriate entity through a particular entity synonym is known as *entity resolution*. Only way one can create a list of synonyms for an entity, usable in web search, is through the web content analysis.

Initial efforts to gather entity synonyms were based upon semantic knowledge and name aliases for most the prominent entities referred in knowledge bases like Freebase [98] and Wikipedia [99]. To collect valid entity synonyms from Wikipedia, redirection pages and disambiguation pages are used.

Following is the literature study in the area of Entity Resolution:

(a) Strube and Ponzetto [100] have talked about retrieving of entity synonyms using Wikipedia. Their work considers two strings to be entity synonyms if their Wikipedia category is same. The problem with this approach is that the size of Wikipedia is much smaller than the web and is limited to prominent entities only. Thus, the approach fails to take up the general purpose common entities.

To find the global and diverse synonyms of an entity, the vast and diversified extent of web can be the ideal source. Therefore, efforts are made to find web based empirical methods to generate the entity synonyms. Let us take a look on some of these efforts:

- (b) Hu et. al. [101] used the redirection relationship between titles of the articles to find out entity synonyms. The approach suffers from the limitation of *title only concept* without taking into the account the page content as a whole.
- (c) Chaudhury et. al. [102] have used the web search to find out the entity synonyms of a given entity name. Their work is limited to only those synonyms which are substrings of the entity name under consideration.
- (d) Malekian et. al. [103] in their work have tried to convert a query into other forms using some features like word reordering, application/addition of modifiers, capitalization of alphabets etc. The work is not directly dealing with entity synonyms but is a contribution to the field of entity resolution in the sense that partial / inexact/ incomplete query can be handled through the system. For example, the queries like *toi*, *time of*, *the times of*, *time of india*, *TOI* can be converted to entity *The Times of India*.
- (e) Some researchers [104-107] have tried to find out the entity synonyms using the reconciliation process in the databases. They have used divergent references of the same real world entity in separate or similar databases as entity synonyms.

The major problem with above citations is that they are unable to take into account the massive and heterogeneous content of the web. Moreover, in most of the cases, the availability of candidate reference is a priori requirement which should not be desirable. Actually the domain of entity resolution requires the automated generation of synonym candidate references from the web covering its vast and heterogeneous profile. These candidate references can then be pruned to create a set of credible entity synonyms.

- (f) One such work has been published by Tao Cheng et.al [1]. In [1], Tao Cheng et.al. proposed a method based upon search data and click data to find the set of entity synonym. They have defined two sets A and L. The set A contains a set of tuples <q, p, r> wherein r denotes the relevance score of a web page p for the query q. The set L contains a set of tuples <q, p, n> wherein n denotes the number of times a user click on page p after issuing query q. The set A finds out the relevance relationship between the query and web page as observed by a search engine. The set L finds out the relevance relationship between query and webpage as observed by search engine users. Based upon this data, they have defined two ratios namely Intersecting Page Count (IPC) and Intersecting Click Ratio (ICR) which measure the strength of relationship between the two candidate strings based upon their surrogates pages identified and actually used (clicked). Larger the values of these ratios for a pair of query strings: more likely they are entity synonyms. The major achievement of the work is their pioneer effort to find the entity synonyms in automated manner using web query and search data. The major limitations of the work are:
 - Click log sparsity problem that occurs when a query is asked by very few users and the clicked documents are even lesser.
 - Inability to make a distinction between entities related to different concepts and classes e.g. *Oracle 10i* and *Oracle 10i tutorial* may be assumed as entity synonyms though they are referring to different concepts.
 - Results are static, domain dependent and cardinality of the synonym set was quite less.
- (g) Kaushik Chakrabarti et.al. [108] proposed a method to overcome the problems of click similarity [1] and document similarity [109]. Their work is based upon

the construction of a Pseudo-Document based upon the collection of all the tokens from all the queries that clicked on a document d. For this purpose, a query log is maintained for a time period and concept of reflexivity (synonym of self) and symmetry (a synonym b means b synonym a) is used. To remove the ambiguity, they have used the criteria of concept class (synonyms should refer to same concept) and auxiliary evidence (clicked documents). A pseudo document similarity function ensures the higher recall without dropping the precision.

- (h) Srikantiah et. al. [110] proposed a mechanism to find the synonyms from the web on the basis of inbound anchor text. They have used Search Engine Result Pages (SERPs) to find candidate synonyms of individual keywords. The technique is scalable and can be applied to dynamic, domain independent data of unstructured web. The synonyms in their case are not entity synonyms but can be adapted to find out the entity synonyms. Their work has been a motivation for the work proposed in this thesis.
- (i) Xiang Ren et.al. [111] proposed a new method of finding the entity synonyms that adopt a "structured" view of an entity by considering not only its string name, but also other important structured attributes. The approach is different from other contemporary methods based upon query log. The approach takes into account the structured view of an entity instead of abstract view related to string name. The work uses a graph based data model involving synonym candidates, web pages and keywords and their interaction relationship in the graph. The drawback of the work is its offline nature and a priori requirement of candidate synonyms.

2.4.1 Limitations of Existing Entity Synonyms finding Methods

The following limitations were identified while discovering entity synonyms using existing approaches:

- 1. No Lexical support as in case of word synonyms.
- 2. Entity references may vary with the global and local reference.
- Synonym set generated through existing methods are not rich and global. They are unable to take into account the massive and heterogeneous content of the web.

- 4. Candidate synonyms are not generated by considering the contexts.
- 5. In many cases, the output is limited to only those synonyms which are substrings of the entity name under consideration.
- 6. In many cases, availability of candidate reference is a priori requirement which is not desirable.
- 7. There is no method for defining an index to assess the quality of synonyms generated.
- 8. Most of the approaches fail to take up the synonyms for general purpose common entities.
- 9. Some of the existing methods work for structured data and it cover the structured web queries with good precision. However, they are not applicable to dynamic and unstructured data i.e. WWW.

These challenges motivated us to propose a novel scheme for generating entity synonyms which is capable of working in a dynamic, online environment and it is not domain specific. The detail of the proposal is available in Chapter IV of this thesis.

2.5 LITERATURE SURVEY FOR RESOLVING CONCEPTS IN THE QUERY

A concept is an abstraction for which the intended set of entities needs to be identified. It is abroad idea generalized from its set of instances e.g. *Bird*, *Actor*, *Books*, *Movie* etc. The biggest challenge lies when a query contains concept(s) which has to be resolved through its meaningful set of instances as it requires awareness about worldly knowledge and the associations within. Consider the query *Best Universities in Europe*.

The easier part of the query is to list all the universities lying in the cities of Europe which only requires worldly knowledge but the difficult part is to decide about *Best Universities* in the absence of any predefined criteria in the query text. Similarly, we can consider queries like *Large Software Companies in Asia, Famous Bollywood Actor and Famous Musician etc.*

The handling of the concept is the most challenging task as its resolution requires the understanding and usage of worldly knowledge keeping in view the underlying associations. The worldly knowledge is too vast to be comprehended and moreover becomes ambiguous, inconsistent and uncertain at many places.

The process of identification of entities associated with a concept in a particular context is known as *concept resolution* or *instantiation*. Concept resolution means to make proper instantiations for the concepts under considerations. It requires:

- Providing the machines/systems the access to large knowledge base related to common sense vocabulary
- Enabling the machines to use this knowledge in an unambiguous manner

Both of these are challenging tasks and can't be executed to perfection. But efforts can be made to accomplish this in a quite appropriate manner.

Enabling the machines, to have the common sense knowledge relating to this world, had long been the goal of the computer scientists. Initially, the interest was academic, relating to the development of intelligent systems covered under the domain of Artificial Intelligence. For this, efforts have been made by many researchers by the creation of manual taxonomies and ontologies. These efforts include the FreeBase (Bollacker et.al., 2008)[98], WordNet (Fellbaum, 1998)[97], Wiki Taxonomy (Ponzetto et.al., 2007)[112], Cyc (Lenat et.al., 1989)[113], YAGO (Suchanek et.al., 2007)[114], KnowItAll (Etzioni et.al., 2004)[115], TextRunner (Banko et.al., 2007)[116], OMCS (Singh et.al., 2002)[117], NELL (Carlson et.al., 2010)[118]and DBPedia (Auer, 2007)[119] etc. Most of these taxonomies have been manually curated and contain limited number of concepts.

The number of concepts in the WikiTaxonomy, YAGO and Cyc are between 0.1-0.5 million, while in FreeBase, WordNet, DBPedia and NELL, their number is in thousands. When one takes into account the volume of common sense knowledge associated with this world, these numbers seem to be extremely small. In the practical applications requiring worldly knowledge (like web search), these resources prove to be quite inadequate. Therefore, a need has long been felt to develop the huge taxonomies and ontologies based upon the web pages in order to:

• Cover large number of concepts and their instances.

- Cover the heterogeneity and versatility of the web.
- Deal with the probabilistic or partial relationship between the concepts and entities in consideration.

One such effort has been in the form of *PROBASE* in Wu et.al. (2012)[120, 121], Song et.al (2011)[122], Lee et.al. (2011)[123], Lu et.al (2012)[124], Liu et.al. (2012)[125] and Wang et.al. (May 2011)[120, 121], a project carried out by Microsoft research Asia which includes more than 2 million concepts and their associated entities. The biggest strength of the PROBASE lies in its two characteristics.

- 1. The taxonomy has been derived from the web, therefore it involves the actually used concepts by the people worldwide involving all sorts of heterogeneity and slang terms.
- 2. The size of the taxonomy is huge and contains very large number of general terms which is much bigger (by one order of magnitude) than its nearest competitors.

The PROBASE by Wu et.al.(2012)[120] includes a large number of concepts and a very large number of associated instances e.g. the concept *actor* has been associated with more than 3000 instances. There are the many concepts that have been associated with hundred thousand instances making it quite difficult to associate the proper set of instances to the corresponding concept. Efforts in this direction include the works of Wang et.al. (2012)[125], Egozi et.al. (April 2012)[126] and Sendhil et.al. (2010)[127]. These works lack depth and operate at quite a surface level. These are discussed below:

- (a) The work proposed by Wang et.al. [26] considers short text as "Bag of Concepts" without taking into consideration the document as a whole.
- (b) Explicit Semantic Analysis proposed by Egozi et.al.[126] uses relatedness analysis based on Wikipedia but neglects the context of words and cannot exactly determine the desired sense of an ambiguous word.
- (c) The work proposed by Sendhil et.al.[127] deals with construction of personalized page view graph for small scale search which is limited to an individual only.

- (d) Fonseca et.al. (2005)[128] generated and organized concept hierarchy from the stored document sets and used it for query expansion purposes with a view to improve precision.
- (e) Lu et.al. (2017)[129] used TREC-VID 2015 (multimedia event detection system) for handling complex concepts in the user query. Their system detected large number of concepts using pre-trained concept detectors for textual-to-visual relation. The problem with this system is the restriction of using only multimedia event detection system for handling the concepts.
- (f) Metzler et.al.(2007)[130] proposed a new mechanism known as latent concept expansion for expanding the term concepts for tasks such as query suggestion and query reformulation.
- (g) Boucennaet.al. (2016)[131] proposed concept-based semantic search for outsourcing the data over cloud after encrypting it. The major restriction using this approach is, all data must be encrypted before being outsource into the cloud and additional overhead occurs for the purpose of encryption & decryption.

This study of literature helped us in identifying following facts about concept instantiation:

- Manually curated worldly knowledge sources such as NELL, Wikipedia, Freebase, DBPedia are insufficient to fill the requirement of the web search engines.
- There is a need to have a worldly knowledge source with the ability to handle all sort of heterogeneous and multidimensional knowledge pertaining to this world.
- PROBASE is an effort in this direction and is publically accessible on the https://concept.research.microsoft.com/Home/Introduction
- Google Humming Bird principle indicates that the user's geographical location, Browsing History and other such parameters can be used to cater the interest of individual user.
- In the WebPages, a lot of concepts are described in the form of slang terms, which are not defined in the lexical sources e.g. the concepts biggie, bigwig, big-wig, heavyweight etc.

- Google has shifted to knowledge graph based search from keyword based search.
- A lot of time is wasted by the search engine if the same query can be interpreted in multiple manners e.g. the string "New York Times Square Problem" can be interpreted as

New York Times and square problem New York and Times Square problem

After identifying the above facts about the present state of affairs regarding the concept instantiation process, following needs were identified to incorporate precision in concept-instantiation process.

- Availability of a credible worldly knowledge source with huge amount of knowledge relating to heterogeneous aspects of the real world.
- Availability of an index in the knowledge source to distinguish between the strength of various candidate instances of a particular concept.
- Analysis of various available contexts in the form of geographical location of the user, past browsing history, IP address and other such trivial information can be of immense help in going for appropriate instantiation as per the need of the user.
- A meaningful parsing of the query text can reduce a lot of burden on the web search engine. So, there should be some appropriate text writing mechanism for resolving between multiple possible meanings of the query text.
- Slang terms should be clubbed with their closest possible formal terms.

Keeping all these aspects in view, a mechanism has been proposed for resolving a concept to its appropriate set of closest instances, using PROBASE, in the presence of available contexts such as IP address, browsing history etc. The details of the mechanism have been discussed in Chapter V of this thesis.

2.6 FUZZY LOGIC

In the preceding text, we have been talking about the need for an index to measure the extent of similarity between various candidate synonyms of a given word/ entity. The

measuring of the index is normally not very precise and is dependent upon various factors used in the synonym identification process. Therefore, two synonyms with not much difference in their similarity indices can be safely considered in the same linguistic category as used in *Fuzzy Sets*. This can also help in designing the automated applications related to web search using *Fuzzy Rule Base* (FRB) system. In this section, we take a brief look at the various aspects of *Fuzzy Sets and Logic*. The architecture of a FRB system for making the required inference has also been discussed.

Fuzzy logic [132] is a form of multi-valued logic derived from fuzzy set theory to deal with approximate reasoning. In contrast to "crisp logic" that has binary values (1/0 or true/false), a fuzzy logic variables may have the value between 0 and 1 indicating the degree of truth, 0 being completely false and 1 being absolutely true and other being partial truth and partial false. Similarly, a Fuzzy set is a superset of conventional (Boolean) set wherein an element can partially belong to a set.

2.6.1 Sets and Logic

A set is a well-defined collection of objects wherein an object either belongs to the set or it does not. This concept is mathematically defined by using a characteristic function, f(A, x)

$$f(A, x) = \begin{cases} 1 & x \in A \\ 0 & x \notin A \end{cases}$$

where A is a set and x is any object. The problem with this type of classical or normal set is that it only talks about complete belongingness or un-belongingness and does not deal with partial belongingness.

To cover this issue, concept of fuzzy sets was introduced by Lotfi A Zadeh [209]. In a fuzzy set, there is a membership function μ that indicates the extent of belongingness i.e. $\mu_A(x) = [0,1]$

where 0 indicates no belongingness, 1 indicates total belongingness and $(0 < \mu < 1)$ shows partial belongingness. The membership can also be expressed as A(x).

2.6.2 Defining a Fuzzy Set

Fuzzy sets represent linguistic concepts such as *very small, small, medium, large, huge etc.* with their interpretation in a particular context expressed through linguistic variables. The states of linguistic variable can be defined in terms of base variable having real number values within a specific range. A base variable is a variable in the classical sense, exemplified by any physical variable (e.g. temperature, pressure, speed etc.) as well as any other numerical variable (e.g. age, interest rate, salary etc.). Each linguistic variable is fully characterized by a tuple (v, T, X, g, m) where

 $v \rightarrow Base variable$

 $T \rightarrow$ set of linguistic terms of v that refer to a base variable whose values range over a universe set X.

 $g \rightarrow$ syntactic rule for generating linguistic terms

 $m \rightarrow$ semantic rule that assigns to each linguistic term t \in T

To illustrate the definition of fuzzy set, let us take the example of human age.

Base Variable: Human Age

Domain of discourse: (0,125) yrs.

Linguistic terms for Fuzzy sets: Child, Young, Middle Age, Old, Very Old.

Semantic Aspect: Linguistic expressions or names of Fuzzy sets should be meaningful.

Syntactic rules: Fig. 2.1 shows the syntactic interpretation of various fuzzy sets.

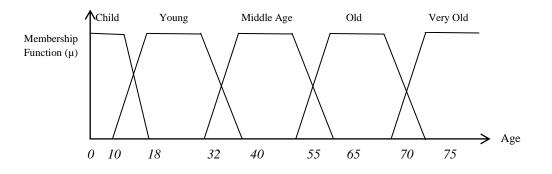

Fig. 2.1 Representation of a Fuzzy Set for base variable age

In this case the set S (the universe of discourse) is the set of people of different age group. In the above diagram five different fuzzy sets are defined such as *Child*, *Young*, *Middle Age*, *Old* and *Very Old* etc. In order to define a fuzzy subset YOUNG, which answers the question like "to what degree is person x young?", we have to assign a degree of membership in the fuzzy subset YOUNG to each person in the universe of discourse. The easiest way to do this is with a membership function based on the person's age. To define the membership function for the fuzzy set young, four possible cases can be there. The value of membership grade is zero when the age is less than 10 and greater than 40, its value increases from 0 when age is between 10 to 18, its value decreases from 1 when age lies between 32 to 40 years, the value is exactly one when age lies between 18 to 32.

2.6.3 Terms Associated with Fuzzy Set

- Membership: It indicates the extent of belongingness of an element to a particular fuzzy set. Its value lies between in interval [0,1]. Larger value of μ indicates more belongingness to the set.
- Support of a Fuzzy Set: Support is that numeric range wherein the μ>0 e.g. sup (child)=(0,18).
- 3. Height of a Fuzzy Set: Height of a fuzzy set is the highest value which μ attains within its support.
- **4.** Normal Fuzzy Set: When the height of fuzzy set is 1, it is known as normal fuzzy set.
- **5.** Subnormal Fuzzy Set: If design of fuzzy set is such that its membership value never reaches '1', then it is a subnormal fuzzy set. A subnormal fuzzy set has height less than one.
- 6. Continuous Fuzzy Set: In an continuous fuzzy set, the values of the element can be real numbers i.e. the domain of fuzzy set is real e.g. Sup(child)=(0,18) represents a continuous fuzzy set whose element can have any real numbers having values from 0 to 18.
- 7. Discrete Fuzzy Set : A discrete fuzzy set has discrete domain wherein the element

under the consideration can have any discrete and quantized value.

e.g. A(x)= $\frac{0.2}{4} + \frac{0.3}{5} + \frac{0.7}{6} + \frac{1}{7} + \frac{0.6}{8} + \frac{0.4}{9}$

- 8. Alpha Cut of a Fuzzy Set: An α -cut indicates a numeric range in the support of fuzzy set A, wherein $\mu \ge \alpha$ it is indicated by A^{α} .
- 9. Strong alpha cut: Support of a fuzzy set can be defined in the form of strong α -cut. A strong α -cut indicates the numeric range within the support of the set wherein the $\mu > \alpha$ it is indicated by $A^{\alpha+}$.
- **10. Fuzzy Rule Base (FRB):** A FRB is a set of deductive reasoning rules which deal with the inference relationship which can be used for decision making process in a control system/ expert system. These rules are stored in the knowledge base of a control system and are selected for the usage in a particular context depending upon the user's requirements. Some example fuzzy rules are as follows:

If temperature is very high then valve opening is large. If pressure is medium then valve opening is very low.

The Fig. 2.2 shows a Fuzzy Control System that uses FRB to control a process. The working of the fuzzy control system is available in various text books. This system was adapted to automate the web search process as shown in the Fig. 2.3.

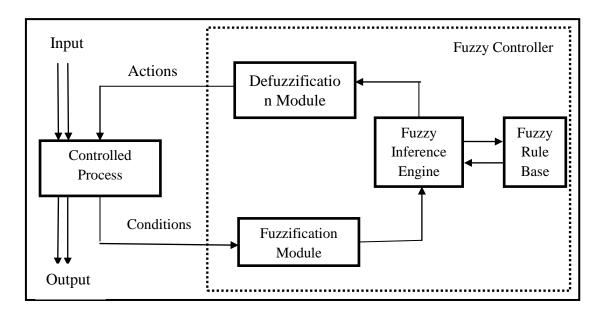

Fig. 2.2 Fuzzy Control System

The Fuzzy Control System (FCS) shown in the Fig. 2.2 was adapted for search engines in order to make the decision as shown in Fig. 2.3 for purpose of query expansion and rephrasing. The adapted system is as shown in the Fig. 2.3

Some example rules used in the query expansion/ rephrasing process are as follows (Here W1 is the original word and W2 is its synonym and similarity index represents the similarity between them in the form of fuzzy set):

If *similarity index is perfectly_similar* use W2 in place of W1 for various purposes like query expansion, query reformulation, word sense disambiguation etc. If *similarity index is quite_similar* use W2 in place of W1 for query expansion, query reformulation, word sense disambiguation etc.

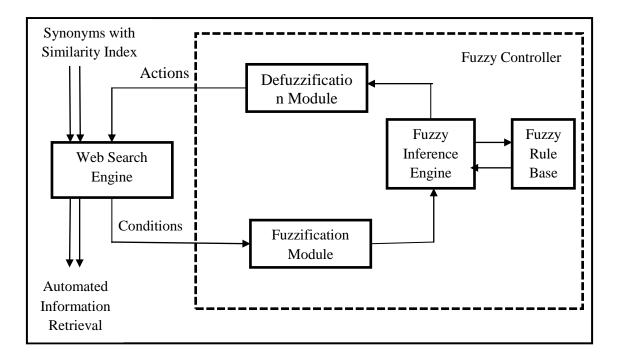

Fig. 2.3 Modified Architecture of Fuzzy Control System

After taking up the details of the study carried out in this chapter, we take up the details of the proposed work in the subsequent chapters.

CHAPTER III SYNONYM RESOLUTION FOR ATTRIBUTE COMPONENT IN QUERY

3.1 INTRODUCTION

In today's digital world, for any topic of interest, information can be retrieved from World Wide Web (WWW). But due to enormous size of the Web, it is not an easy task to retrieve exact information. To overcome the problem, variety of search engines are available online which provide an easy to use interface wherein a user can express his/her information requirements in the form of query. A search engine has to ensure the retrieval of desired information content as per the requirements of user. Query being a very short piece of text has to be critically evaluated for its unambiguous and exact meaning. The various pages available on the WWW which can be relevant to the user's query may not have exactly same matching words as used in the query. Thus, it is a requirement that the synonyms of the words used in the query be chosen in an appropriate manner so that more and more relevant pages included with nonrelevant being discarded. This mandates that an appropriate mechanism be devised to create the synonyms of the words based on the huge real world data which is quite feasible in today's technological scenario. Also, it is desirable that the extent of similarity between a word and its synonym be quantified to enable the search engines in taking a rational decision for the purpose of query substitution and expansion. This chapter takes up this task and proposes a mechanism for finding appropriate synonym set for a given word and to express the extent of similarity between them using both numerical measures and fuzzy sets. The work has been carried out for attribute component of the query.

After the inception of the Web, need for the search of meaningful and appropriate synonyms has been felt like never before. The requirement is no longer mere academic but is necessity for appropriate and relevant information retrieval from the web. The manually curated lexical resources like WordNet [97], YaGo [114], Cyc [113] are unable to meet this requirement due to gigantic size and heterogeneity of web. Therefore, a lot of efforts have been carried out in the past to find out the word similarity for finding meaningful synonyms using web pages. These works have been

discussed in literature survey of this thesis in Chapter II. Before taking up the proposed work, we take a look on the limitations of these contributions.

3.2 LIMITATIONS OF EXISTING WORD SIMILARITY METHODS

The existing word similarity approaches suffer from the following limitations:

- Mere page count based approaches used in [10, 11] are quite crude.
- Text snippets is based approaches [133] are dependent upon choice of snippet length. Both short and long snippets have their own merits and demerits.
- Word taxonomy based approaches [95] depend upon various heterogeneous aspects.
- Processes like concept identification and relation identification are perception dependent [17].
- Word embedding models used in [134] are not much consistent and their applicability depends upon case to case.

These challenges motivated to direct the research in calculating the word similarity using real world data.

3.3 PROPOSED WORK

The semantic aspect of a query is essential while determining the information required by the user using available information retrieval tools. For retrieving documents, which are semantically similar to the query submitted by user, it is required that users' query be expanded to cover more terms which are semantically similar. A pure keyword based information retrieval system is unable to use the concept of semantic similarity thereby missing the major chunk of useful pages. The search engines, if do not take into account the context of a query and unseeingly use the online lexical resources, may lead to fetching of large number of undesired pages which are otherwise not essential. To defeat this weakness, it is required that query be expanded through meaningful semantic expressions using context set. This appropriate choice requires the precise knowledge about semantic similarity between original word in the query and the word to be substituted. But the precise measurement of the semantic similarity is a challenging task as most of words in a natural language have context dependent meaning. Keeping this need in view, this chapter focuses on a novel approach which tunes the lexical resources wherein the derived synonyms of a word are also provided with their applicable context.

Since it is not possible to explore whole of the Web, therefore for finding the synonyms, help of multiple corpora, with wide range of genres and with each one containing huge set of documents were taken. The snapshot of different Corpuses used to extract context related to a word is shown in Appendix A.

The work presented here takes into consideration the attributes present in the query. The attribute in a query is a word that describes a particular quality of the subsequent word in the query. The subsequent word whose qualities are described using the attribute can be considered as its context. For example, if two or more attribute words have similar context set then they must be synonyms. The proposed work is based upon the following strategies:

- Identification of the context set of the attribute word under consideration using multiple corpora.
- Adaptation of existing similarity measures for computing the similarity between various context sets.
- Computation of similarity extent between the contexts sets using different adapted similarity measures.
- Normalization of similarity scores computed through various adapted similarity measures.
- Designing of fuzzy sets to give the computed similarity a meaningful linguistic expression.

The proposed work can contribute to the web search technology and the linguistic world in following manner:

- Fuzzy sets generated can be used in the creation of the Fuzzy Rule Base (FRB) for automated use of computed similarity index for applications like web search.
- The new generation lexical resources can also be augmented with the applicable similarity index while defining the synonyms of a word.

• The context set of a word can also be defined to ensure its proper usage.

Thus, the attribute synonyms promise to deliver more precise results for a semantic search rather than keyword based search.

Before going for actual process, let us take up the details of the online resources used in the proposed work.

3.3.1 The Resources

Various online lexical resources and the corpora have been utilized as knowledge base for the proposed work, the details of which are given as under.

(i) WordNet

WordNet is one of the most influential online lexical resource developed by Miller et.al.[97] at Princeton University. It has combined features of both dictionary and thesaurus, based upon psycholinguistic theories of human lexical memory. It consists of set of English nouns, verbs, adverbs and adjectives organised into synsets and having various lexical-semantic relations between them. In this work, this resource is used to retrieve the set of synonyms for substituting the input word used in the query.

(ii) Corpora

To identify the contexts related to a word, four different corpora are considered namely Coca Corpus [135], BNC Corpus [136], Wikipedia Corpus [137] and GloWbE Corpus [138]. The size of each corpus along with the other details is shown in Table 3.1. The reason for choosing the above corpora is their ability to allow search on the basis of word, phrase, part of speech and synonyms. For the purpose of context identification, the size of text window is taken as 2 because a shorter window ensures the proper relevance of context. The input word is searched into the corpus to extract context related to a word. These contexts are then used to find semantically similar words.

| Corpus | Genres | No. of words | Type(s)of |
|-----------|--|--------------|-----------|
| | | | documents |
| Coca | spoken, fiction, popular magazines, | 520 million | Text |
| Corpus | newspapers and academic texts. | | |
| BNC | spoken, fiction, magazines, newspapers and | 100 million | Text |
| Corpus | academic | | |
| Wikipedia | documents related to microbiology, | 1.9 billion | Text |
| Corpus | economics, basketball, Buddhism, or | | |
| | thousands of other topics. | | |
| GloWbE | Any type of data related to newspaper, | 1.9 billion | Text |
| Corpus | magazines and academic. | | |

Table 3.1 Details of Corpora for Consideration

The relational database design of these corpuses allows complex queries to be executed in two or three seconds. These corpuses are used to extract context related to a word and helps to build next generation lexical resource. The upcoming section throws light on the foundation of the proposed work.

3.3.2 Proposed Synonym Resolution Approach for an Attribute using Contexts

The main objective of the work is to propose a synonym resolution method for attributes in a query based upon the immediate context of the said attribute in various corpora. The outcome of the work includes context set identification for a word and computation of an index indicating the extent of semantic similarity between a pair of words. The computed index has been fuzzified into a fuzzy rule base for the purpose of automation and its usage into the web search engines and other such applications. The proposed architecture for finding the semantically similar word of the attribute word in consideration is shown in Fig. 3.1.

The proposed approach uses WordNet and exploits various corpuses to identify the context set for the words under consideration. The reason for these choices is the extensive coverage of almost every branch of knowledge by them and the volume of available data. Initially the input attribute word is searched in the WordNet for extracting the set of available synonyms. Thereafter, four different corpuses have been used to identify the context set for both the word under consideration and its chosen synonym. The list of all possible contexts are taken out by considering the

union of contexts taken from all the four corpora. The list of most commonly used contexts is taken out by considering the intersection of these contexts. Now, the extracted list of synonyms is checked for similarity with the input adjective word. In the literature, WebJaccard, WebOverlap and WebDice are different types of standard indices used to compute similarity index between input word and its synonym word on the basis of page-count. All these indices have been modified in the proposed algorithm to use the context set cardinality instead of page count. Now, one can choose an appropriate index and use it for fuzzification. Our preferred choice is Modified WebJaccard as it takes into account both union and intersection aspect while calculating similarity.

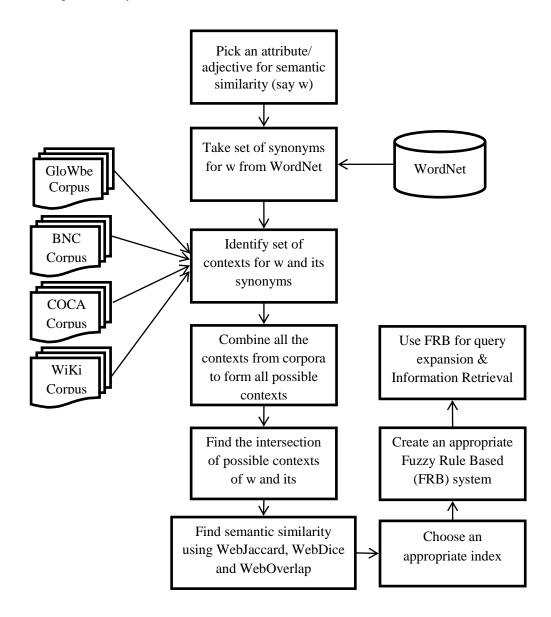

Fig. 3.1 Proposed Architecture for finding the Semantically Similar Word

To enable the automated tools in making the intelligent decision on the basis of the additional information created in the work, the similarity index has been fuzzified through the design of appropriate fuzzy sets. This will help the information retrieval system in following manner:

- (a) Minor differences arising out of computation due to the choice of search engine, set of documents, dialects etc. are eliminated, as two close values would normally be residing in the same fuzzy set.
- (b) The fuzzy sets created in such a manner can be used for intelligent decision making by creating a Fuzzy Rule Base (FRB) that can be run on an appropriate fuzzy inference engine.

3.3.3 Creating Semantic Similarity Index and Applying Fuzzy Rule Base (FRB)

Beginning with the details of proposed work, the following algorithm has been designed:

(a) Algorithm for finding the semantically similar word

Input: The word *w* (adjective), *n* sets of word corpus

Output: Set of semantically similar words of *w* along with similarity index, Fuzzy Rule Base (FRB)

Step1: Choose a candidate word for finding semantic similarity, say w

Step2: Choose a set of *n* corpora.

Step 3: For each corpus *i*, identify set of contexts for *w*, C_i

Step 4: Compute $C_{pw} = C_1 \cup C_2 \cup \ldots \cup C_n // Possible list of contexts for w$

Step 5: Compute $C_{cw}=C_1 \cap C_2 \cap \ldots \cap C_n$ //List of most commonly used contexts for w Step 6: Augment C_{pw} and C_{cw} in lexicon along with the word w.

Step 7: Let S be the set of synonyms for w obtained from a lexical resource, say WordNet.

Step 8: for each $x \in S$, Compute C_{px} and C_{cx} using step 3-5 //List of possible and commonly used contexts for x.

Step 9: Compute similarity index between w and x using WebJaccard co-occurrencemeasure.// Context set cardinality is used instead of page count.

Modified_WebJaccard (*w*, *x*)= $|C_{pw} \cap C_{px}|/|(C_{pw} + C_{px} - C_{pw} \cap C_{px})|$

Step10: Normalize the computed co-occurrence to a range $[r_1, r_2]$.

Step11: Use $[r_1, r_2]$ as domain of discourse to create fuzzy sets expressing the extent of similarity between the words *w* and *x*. Let the fuzzy sets be: *not_similar*, *poorly_similar*, *medium_similar*, *highly_similar*, *extremely_similar*.

Step12: Create an appropriate Fuzzy Rule Base (FRB) to implement the computed similarity in automated manner.

Step 13: Use FRB for query expansion and information retrieval.

Step 14: Stop

(b) Explanation and implementation of proposed algorithm

The proposed algorithm was implemented using a very commonly used word *beautiful*. The explanation behind picking the word *beautiful* is because of its commonness and availability of its large of synonyms applicable to different varieties of contexts. Its available synonyms were discovered using the available lexical resource *WordNet* thereby creating the set *S*. With the goal of context identification, the size of text window (i.e. the maximum distance between the focus word and its contextual neighbours) was taken as 2 (two) due to the fact that a shorter window ensures the proper relevance of the context. In addition, since the word is of adjective type, a window of size 2 is quite appropriate. For different sort of words, the size of the window can be adjusted. The calculation of C_{pw} (possible list of contexts for word *w*) and C_{cw} (list of most commonly used context for the word *w*)using multiple corpora guarantees the elimination of bias that may occur in a specific corpus.

To apply the algorithm, few synonyms of *beautiful* were taken from the WordNet namely: *Pretty, Lovely, Gorgeous, Glorious, and Stunning*.

The extracted list of synonyms was checked for similarity with the input adjective word. The different corpora (here four) were used to identify the contexts related to a given word and its synonyms. Then list of all possible contexts were taken out by considering the union of contexts from all the four corpora. The list of most commonly used contexts was taken out by considering the intersection of contexts using the four corpora. In the literature, *WebJaccard*, *WebOverlap* and *WebDice* are different type of standard indices are used to compute similarity index between input word and its synonymous word on the basis of page-count. All these indices have

been modified in the proposed algorithm to use the context set cardinality instead of page count. It is for this reason that they have been named as Modified_WebJaccard, Modified_WebOverlap and Modified_WebDice respectively.

The computed index has been normalized to the range [0,100] through the use of a normalization factor. The purpose of normalization is to create a relative standing between the various candidate synonyms through a standard level of parity e.g. percentage. The so computed normalized index can also be used as the membership indicator in the corresponding fuzzy set. The range [0,100] is then used as a domain of discourse to create fuzzy sets expressing the extent of similarity between two words through linguistic expressions. The fuzzy set framework created in such a manner leads to the creation of a Fuzzy Rule Base (FRB) that can be used for automated query expansion and information retrieval through the usage of computed normalized similarity index.

The major issue here was the calculation of normalization factor. The empirical calculation of this factor may slightly vary with the perception of the designer. In our case, it is considered that two different words are almost similar (assuming that they cannot be exactly similar) at the level of 100 if their context set is at least 80% same as that of the smaller context set and sizes of their context sets do not differ by 25%. Of course, the designer of the automated system can choose different values as suited to their application and the precision requirement.

To illustrate the normalization process, let us take two words w1 and w2 with cardinality of their context sets as $|C_{w1}|$ and $|C_{w2}|$.

Let $|C_{w1}| = 100$, $|C_{w2}| = 125$

Here difference in cardinality of context set is 25%

It is assumed here that context set matching is 80% of the smaller context set i.e.

 $|C_{w1} \cap C_{w2}| = 80$

Here, $|C_{w1} \cup C_{w2}| = |C_{w1}| + |C_{w2}| - |C_{w1} \cap C_{w2}| = 145$

Expected normalized similarity value=100

This data leads to values of different indices as follows:

Modified_WebJaccard= 80/145=0.55

Modified_ WebOverlap as 80/100=0.80

Modified_ WebDice as 160/225=0.71.

The normalization factor under the circumstances for these indices will be 100/0.55=182, 100/0.80=125 and 100/0.71=141 respectively subject to maximum of 100. The so computed normalization factor has been used in the Tables 3.3 to 3.9 of this chapter to compute the normalized similarity index.

(c) Example Context Sets

Given below are possible and commonly used context sets for the example word 'beautiful' and its synonyms.

List of possible contexts for word Beautiful:

 $C_{pw}=\{$ area, art, baby, bay, beach, black, blonde, blue, body, book, boy, bride, building, children, church, city, cloth, color, country, countryside, creature, dark, daughter, day, dreamer, dress, evening, eyes, face, family, female, fish, flower, game, garden, girl, hair, head, home, house, image, island, job, lady, lake, landscape, liar, life, little, maiden, man, mind, morning, mother, mountain, movement, music, name, natural, new, night, object, old, park, part, person, photo, picture, piece, place, post, princess, red, river, room, scenery, setting, sight, singing, skin, smile, song, soul, sound, south, spring, story, stranger, summer, surrounding, temple, thing, town, valley, view, village, voice, way, weather, wedding, white, wife, woman, word, work, world, young}

Here |C_{pw}|=107

List of Commonly used contexts for word beautiful:

 C_{cw} ={baby, beach, city, country, daughter, day, face, flower, garden, girl, lady, person, place, scenery, thing, view, voice, wife, woman, young}

Here |Ccw|=20

List of Commonly used contexts for word Pretty:

C_{CX1}={girl, woman ,face, picture}

Here |C_{cx1}|=4

List of possible contexts for word Pretty:

 C_{PX1} ={ baby, blonde, boy, busy, child, cloth, committee, dress, eyes, face, garden, girl, guardian, horse, lady, light, maid, picture, pink, poison, sight, soldier, solid, song, sweet, thing, village, visitor, woman}

Here |C_{px1}|=29

List of Commonly used contexts for word Lovely:

 C_{CX2} ={bone, children, city, couple, daughter, day, eyes, face, family, garden, girl, guy, lady, man, night, person, place, sight, song, story, thing, voice, wife, woman}

Here |C_{cx2}|=24

List of possible contexts for word Lovely:

 C_{PX2} ={afternoon, angel, area, article, ballad, bank, blog, blue, body, bone, book, boy, bride, bunch, butcher, carrot, children, city, cloth, color, colour, country, countryside, county, couple, daughter, day, dinner, dog, dream, dress, egg, evening, eyes, face, family, feather, feeling, flower, food, friend, garden, gift, girl, green, guy, hair, head, holiday, horse, hotel, house, idea, idol, image, kid, lady, land, lane, light, little, lock, lunch, man, meal, moment, music, name, night, old, party, person, photo, picture, piece, place, princess, reader, red, rita, room, rose, seat, setting, shade, sight, smell, smile, song, sound, spot, story, stuff, summer, surprise, tea, thing, thought, time, town, valley, view, voice, war, way, weather, white, wife, woman, word, world, young}

Here |C_{px2}|=112

List of Commonly used contexts for word Magnificent:

 C_{CX3} ={achievement, bird, building, city, collection, display, example, garden, house, job, old, performance, piece, scenery, sight, view, work}=17

Here $|C_{cx3}|=17$

List of possible contexts for word Magnificent:

 C_{PX3} ={achievement, amberson, animal, architecture, art, away, backdrop, baroque, bastard, beach, beast, beauty, bird, black, blue, body, book, bridge, bronze, building, but, butcher, career, castle, cathedral, century, church, city, cliff, collection, contribution, coral, country, countryside, courage, court, creation, creature, day, desolation, dining, display, dog, dress, effort, entrance, event, example, experience, figure, five, four-poster, fraud, frigatebird, funeral, game, garden, gift, goal, golden, gothic, grey, hall, head, history, home, horse, hotel, house, job, journey, lake, landscape, library, life, man, mansion, marble, medieval, mile, montague, monument, moody, mountain, muraco, natural, new, obsession, old, opportunity, palace, panorama, park, performance, physique, piece, place, player, record, red, renaissance, response, ring, room, scale, scenery, season, second, set, setting, seven, show, sight, site, six, sound, specimen, spectacle, stained, state, stone, structure, sunset, surrounding, temple, thing, tomb, tree, victory, view, villa, vista, voice, way, white, woman, wooden, work, world, yankee, young}

Here $|C_{px3}| = 141$

List of Commonly used contexts for word Good_Looking:

All the mentioned sets are utilized during the implementation and analysis of proposed approach.

3.4 RESULT AND ANALYSIS

Table 3.2 represents the computation of various indices based upon the extracted information. Results have been normalized using the normalization factor described in previous section of this chapter. The computed results have been compared with UMBC toolkit, [139] in Tables 3.3 to 3.9. The toolkit uses statistical method that is based on Latent Semantic Analysis (LSA) and distributional similarity. The whole process is automated and can be trained using different corpora. The technique used in this toolkit assumes that the semantics of a phrase is compositional on its component words. The concept and relation similarity can be found for noun, verb, adjective and adverb using either refined Stanford Webbase corpus [140] or LDC English Gigaword corpus [141].

The computed results have been utilized for generation of a Fuzzy Rule Base to be used for further applications.

3.4.1 Fuzzy Rule Base

The computed results show quite an agreement with the toolkit. The errors are generated due to various factors owing to the usual ambiguity of the natural language which justify the need for fuzzification. Also, it is hard for a user to select appropriate one out of the available values, therefore fuzzification plays a vital role. The domain of discourse for the fuzzy sets is [0,100] and the chosen fuzzy sets are:

NS: Not_Similar PrS: Poorly_Similar SS: Somewhat_Similar QS: Quite_Similar PfS: Perfectly Similar

Now, one can choose an appropriate index and use it for fuzzification. The membership graph of various fuzzy sets is shown in Fig. 3.2.

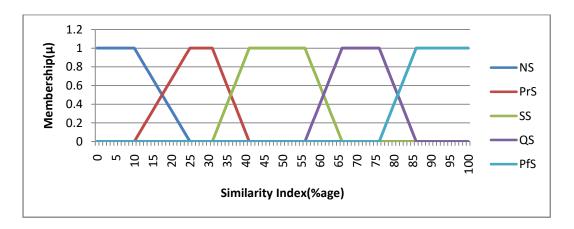

Fig. 3.2 Membership Graph of various Fuzzy sets

The design of fuzzy sets follows the Fuzzy Rule Base (FRB) needed for automated decision making. The design of fuzzy sets and the FRB is illustrative and designer of the system can modify them as per the requirement.

3.4.2 Applications of Fuzzy Rule Base

Following are the possible application areas where the proposed FRB can be applied.

- If the similarity index is *perfectly similar* use W2 in place W1 for word sense disambiguation, web page classification and query expansion.
- If the similarity index is *quite similar* use W2 in place W1 for query expansion and web page classification.
- If the similarity index is *somewhat similar* use W2 in place W1 in query expansion.
- If the similarity index is *poorly similar* use W2 in place W1 for query expansion after checking the context.
- If the similarity index is *not similar* do not use W2 in place W1.

3.4.3 Format of Next Generation Lexical Resources

The ultimate goal of the work done in this chapter is to augment the existing lexical resources by adding the similarity index and the context set in which two words can be semantically similar. The desired format of next generation lexical resources will look as follows:

Modified Lexical Resource

<Chosen Word> : <Set of possible contexts> <Set of most commonly used contexts> <Synonym-1>:<similarity index> <common context set> <Synonym-2>:<similarity index> <common context set> <Synonym-k>:<similarity index> <common context set>

The above format proposed for the lexical resources not only provides the set of synonyms but also provides the extent of similarity in the normalized manner. The similarity index can be used in the automated manner through the creation of Fuzzy Rule Base for the purpose of query rephrasing and word sense disambiguation.

The augmentation of the context set with the word enables the automated resources like web search engines in dealing with the query sense making the web search process relevant.

3.5 SUMMARY

This chapter has described an efficient and effective synonym resolution approach by finding semantic similarity between words depending upon their contexts. To avoid biasness multiple corpora have been considered for implementation. The similarity index has been computed on the basis of commonality of the contexts. Various benchmark indices have been used to find the similarity index and the results have been normalized. The results obtained have been compared with a standard toolkit for the purpose of authentication.

It may be observed that the benefit of the proposed technique is to overcome the problems of synonymy and polysemy over the information retrieval field, by finding the semantically similar words with respect to query. Moreover, an intelligent approach is used that uses the context sets to identify the words that are semantically similar. This approach also helps in enrichment of lexical resources.

The next chapter introduces a new method to find the synonyms when an entity is used as a query component instead of the attribute.

CHAPTER IV DYNAMIC ENTITY RESOLUTION

4.1 INTRODUCTION

In the first chapter of the thesis, we described that a query contains four basic components: *keywords, attributes, entity* and *concept*. In the previous chapter the attribute component of the query was considered and it was explained how attributes can be replaced by their appropriate synonyms for the purpose of query expansion, resolution and reformulation. In this chapter, the entity part of the query has been taken care of and it is described how web can be used to create meaningful synonyms for a given entity to facilitate query expansion, resolution and reformulation. Before taking up the entity resolution process, let us take up the basic terminologies associated with the entities.

4.2 BASIC TERMINOLOGIES

Entity: An entity refers to a place, person, thing, event or abstraction having a distinct and separate existence from other instances of similar attributes. The reference to the entity may be local or global depending upon the context of the underlying domain.

Entity Identifier: Formal nomenclature for the entity e.g. *The Times of India, The Hindustan Times, Kabhi-Kabhi, Dilwale Dulhaniya Le Jayenge, i20, Santro Xing,* etc.

Entity Synonyms: A list of formal and informal identifiers referring to the same entity i.e. commonly used alternative name references to describe the entity under consideration e.g. *TOI* and *Times of India* refer to the same entity. In the same way, *Tere Bin Laden-2* and *Tere Bin Laden dead or alive* are not different.

To mathematically define the concept of entity synonyms, consider the following assumptions:

- S: Universal set of strings over an alphabet
- E: Universal set of entities

 E_X : A list of entities over the domain X for example E_{Movies} will be a set of entities over the movie domain.

Now we can define a function F having two arguments, the first one being an arbitrary string $s \in S$ and the second one being the entity domain E_x . Then the function F(s, E_x) \rightarrow e where E_x maps the string s to a single entity e or a set of entities in the global domain E which is a superset of E_x , thereby making a local reference as global.

Entity Synonym: Two strings s1 and s2 defined over the set S are said to be entity synonyms iff $F(s1, E_X) = F(s2, E_X)$

Entity Hyponym: A string s1 is a entity hyponym of the string s2 (both defined over the set S) iff $F(s1, E_X) \subseteq F(s2, E_X)$.

Entity Hypernym: A string s1 is a entity hypernym of the string s2 (both defined over the set S) iff $F(s1, E_X) \supseteq F(s2, E_X)$.

The problem of finding the entity synonyms of a string s can be mathematically described as a situation to create a set Ws of strings w's such as:

 $Ws = \{ w \in S \mid F(s, E_X) = F(w, E_X) \}$

The set $W = \{w1, w2, \dots, wk\}$ contains entity synonyms for the string s over the domain X. Given a string s over the domain X, we have to find out W in the context of E_X .

4.3 EXISTING WORK AND THEIR DRAWBACKS

The work discussed in the literature survey forms the basis for objectives of the proposed work with following set of identified problems:

- Synonym sets generated through existing methods are not rich and global. They are unable to take into account the massive and heterogeneous content of the web.
- 2. Candidate synonyms are not generated by considering the contexts.

- 3. In many cases, the output is limited to only those synonyms which are substrings of the entity name under consideration.
- 4. In many cases, availability of candidate reference is a priori requirement which is not desirable.
- 5. Some existing approaches only consider relationship between titles, so they suffer from the limitation of *title only concept* without taking into the account the page content as a whole.
- 6. There is no method for defining an index to assess the quality of synonyms generated.
- 7. Most of the approaches fail to take up the synonyms for general purpose common entities.

4.4 SIGNIFICANCE OF THE PROPOSED APPROACH

The solution to the above listed challenges is to design a novel mechanism to generate quite rich and credible set of entity synonyms that can be help the search engine to refer to an the entity under consideration in different ways. Entity synonyms generated through the proposed method have an edge over prevailing mechanisms, as it provides:

- More relevant set of entity synonyms (both in terms of quantity and quality)
- An index to access the quality of generated entity synonyms.
- Fuzzification of the Index for the purpose of automation.

The work will contribute to web-search in following ways:

- Improved search relevance
- Improved user experience
- Query auto suggestion
- Creation of entity dictionary
- Meaningful query expansion for the queries involving entities.

4.5 PROPOSED APPROACH

This section presents a method for discovering entity synonyms, with application to the Web Search. The proposed work comprises the iterative utilization of Search Engine Result Pages (SERPs), extraction of context from the URL, extraction of anchor text, webpage titles & snippets and candidate synonyms from query log. The proposed approach generates the set of entity synonyms using static and dynamic data. For the purpose of static data, web query log is used as an offline source. For dynamic data, online web content is used. A fragment of the query log is shown in Appendix D.

The procedure starts with the issuance of query (an entity) by the web client on the search engine interface. The search engine gets the query and returns the result pages referred to as SERPs. In the proposed approach, the Universal Resource Locators (URLs) of these SERPs are looked in the query log to get the candidate synonyms. The title and snippets of the URLs of these SERPs are utilized to obtain the contexts. By this method, first level of candidate entity synonyms are obtained. Now, these initial set of candidate synonyms are combined with contexts in order to explore more entity synonyms using dynamic web data.

A new query is then issued to the search interface using a combination of a candidate synonyms and the context related to an entity to obtain a new set of SERPs.

For extracting rich and more focused entity synonyms, the dynamic web content is used. For this purpose, the algorithm based on *Inbound Anchor Text* is applied. The anchor text that is the clickable text in a hyperlink and is relevant to the page a user is looking for, rather than generic text. The process actually begins whenever a new query which is obtained from static method is entered onto the search interface. The search interface returns a list of URLs. These URLs are collected to form a list of parent URLs (PUs).

Next, these PUs are further treated as input to generate sub parent URLs (SPUs). Thereafter, SPUs are visited one by one and downloaded web pages are retrieved in form of child documents. All pairs (anchor text, link) contained in child documents are collected in a hash map of anchor text and its corresponding URL as a set of child

URLs. The child URLs contained in the hash map is compared with the parent URLs. If there is match between child URL and parent URL, then anchor text corresponding to child URL will act as a candidate entity synonym. The child documents are also used to find the context for input entity.

The context used by the algorithm is also retrieved using title and snippet of child documents. Context obtained are combined with the original entity (query string) to produce another set of candidate entity synonyms. Sub parent URLs are also compared with parent URLs, if match occurs then the trailing part of sub parent URL will act as a candidate entity synonyms.

Thus, entity synonym is extracted using four things:

- The user history log database
- Child map in case of match
- Trailing part of sub parent URL
- Combination of query and context obtained from child documents

The detailed process is shown through a flowchart as shown in Fig. 4.1. The snapshots of the implementation results using various techniques including the proposed one is shown in Appendix B.

4.5.1 Generation of Similarity Index

After getting the candidate synonyms, similarity index is computed between the actual entity word and the candidate synonyms using *Web Jaccard* [142] method. The index values obtained thereof are normalized between the range [0, 1]. Taking the normalized fuzzy value as the outline criteria, fuzzy sets are defined to express the quality of synonyms linguistically. These fuzzy sets are then used in Fuzzy Rule Base (FRB) for the automated application of entity synonyms in the web search process. Fig. 4.1 demonstrates the strategy to generate optimized set of entity synonyms.

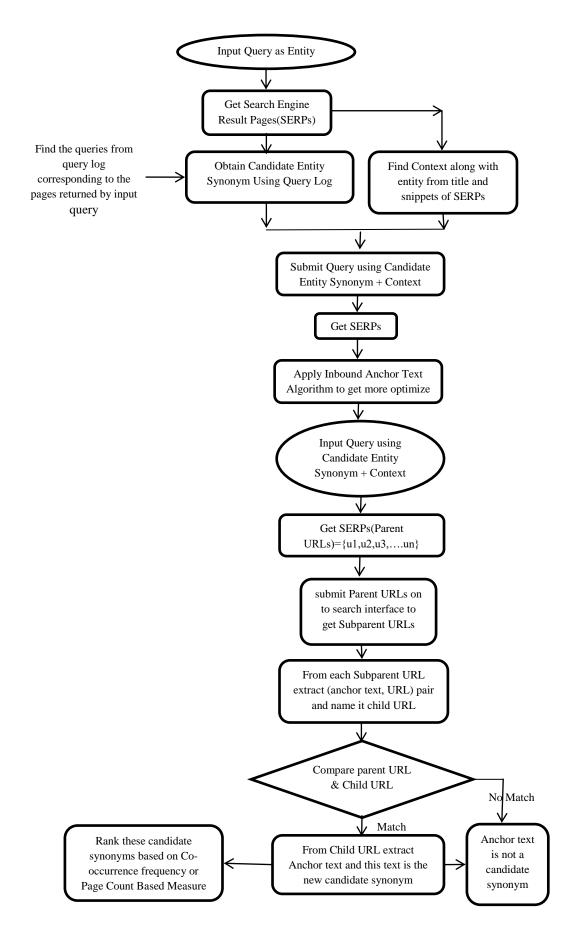

Fig. 4.1 Strategy to Generate Optimize Entity Synonyms

4.5.2 Dataset Description

Various online resources and web data (online) have been utilized for the purpose work, the details of which are given as under:

(i) Query Log

Query logs are used for improving user search experience because they act as a resource to explore the history of the user for a specific time period. As a dataset, AOL[143] query log for the period of one year is used. This log consists of more than 40 million entries. The structure of the query log is shown in Table 4.1.

| Anon ID | Query | Query Time | Item Rank | Click URL |
|---------|------------------------|---------------------|-----------|---------------------------------|
| 5383757 | times of india | 2006-03-13 12:36:09 | 1 | http://timesofindia.indiatimes. |
| | | | | com |
| 5175703 | Near death experiences | 2006-05-09 22:36:08 | 2 | http://www.nderf.org |
| 470385 | george bush | 2006-03-30 15:44:00 | 3 | http://bushlibrary.tamu.edu |

Table 4.1 Structure of Query Log

The data set includes (AnonID, Query, QueryTime, ClickedRank, DestinationDomainURL), whose descriptions are given below:

- AnonID: An anonymous user ID number.
- Query: The query issued by the user
- QueryTime: The time at which the query was submitted for search.
- ItemRank: If the user clicked on a search result, the rank of the item on which they clicked is listed.
- ClickURL: If the user clicked on a search result, the domain portion of the URL in the clicked result is listed.

Each line in the above table represents one of two types of events:

- 1. A query that was NOT followed by the user clicking on a result item.
- 2. A click through on an item in the result list returned from a query.

Here, the ClickURL attribute in the table get matched with the Search Engine Result Pages (SERPs) to obtain the basic set of candidate synonyms. The very large file (query log) is used after splitting into a number of sub files, and then parallel processing is used to scan these files to get the desired results.

(ii) Web Data

Web data is the data that comes from large or miscellaneous number of sources. Web data are developed with the help of Semantic Web tools such as Resource Description Framework (RDF), Web Ontology Language (OWL), and SPARQL (Simple Protocol and RDF Query Language). Web content is textual, visual, or aural in nature and can be encountered as part of the user experience on websites. As a part of dynamic data, web data is used.

4.5.3 Implementation Details of the Proposed Approach

Fig. 4.2 describes the basic methodology of the proposed work and Fig. 4.3, Fig. 4.4 and Fig. 4.5 shows the architecture for different component of the proposed work.

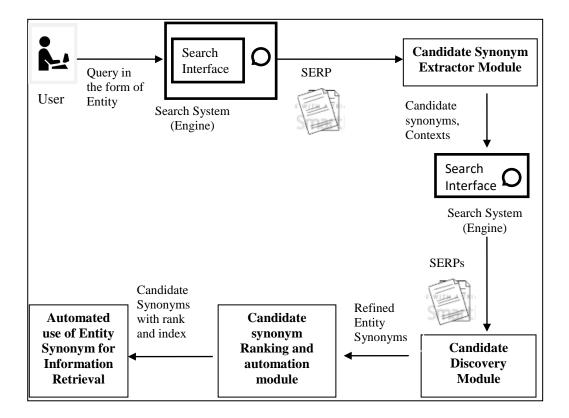

Fig. 4.2 Basic Architecture of Proposed Methodology

The purpose of different modules shown in Fig. 4.2 is as follows:

(i) Candidate Synonym Extractor Module

- This module matches the URLs returned on search interface with the URLs present in Query Log for obtaining the basic set of candidate synonyms
- It also finds the context from snippets and titles.
- It combines the basic set of candidate synonyms with the contexts to extract all possible combinations of candidate synonyms.

The detailed process of candidate synonym extractor module is shown in Fig. 4.3.

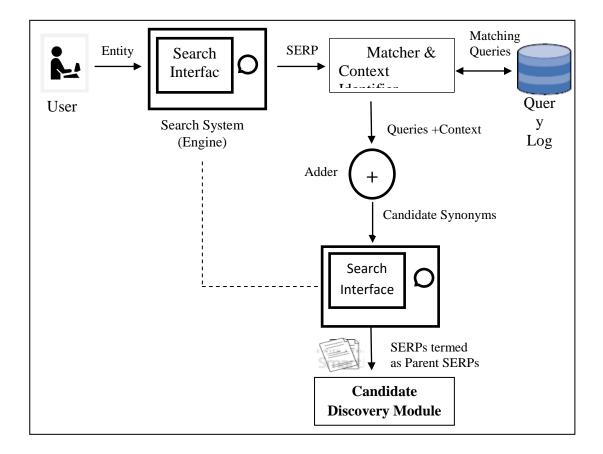

Fig. 4.3 Architecture of Candidate Synonym Extractor Module

(ii) Candidate Discovery Module

- This module finds the SubParent URLs after issuing Parent URLs on browser.
- It downloads the SubParent URLs to get the child pages.
- It extracts <anchor text, URL> pair to obtain child URLs.

- It matches the Parent URLs with Child URLs and obtains candidate synonyms as an anchor text.
- From downloaded child pages, it also extracts context from snippets and title. Contexts are also obtained from trailing part of Parent URLs.
- It combines all candidates generated from this module to get the refined set of candidate synonyms.

The process of entity candidate discovery module is depicted in Fig. 4.4.

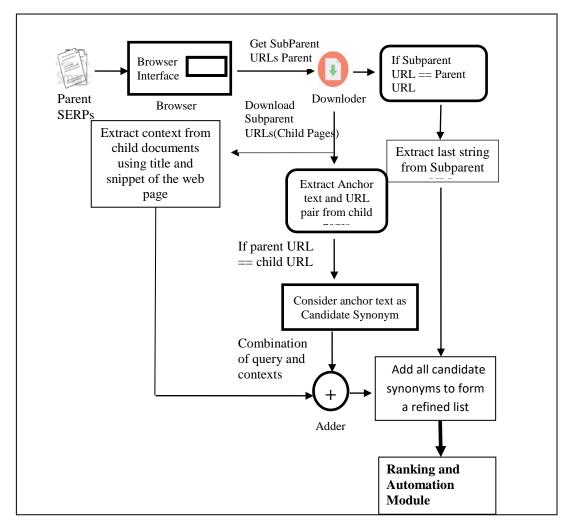

Fig. 4.4 Entity Candidate Discovery Module

(iii) Candidate Synonym Ranking and Automation Module

• This module calculates the page count for entity, page count for refined set of candidate synonyms, page count for entity and

refined set of candidate synonyms, page count by combining entity or refined set of candidate synonyms,

- It then applies WebJaccard measure to find the similarity index.
- It also applies normalization and ordering to obtain normalized and sorted index.
- Then fuzzification is done to obtain the fuzzy set.

The process of candidate synonym ranking and automation module is depicted in Fig. 4.5.

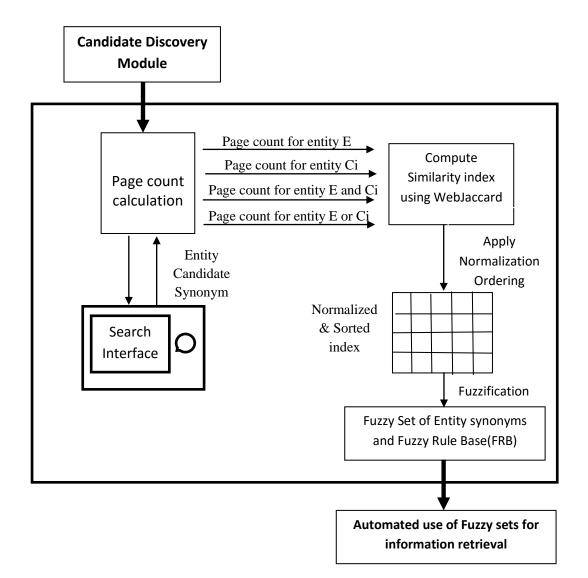

Fig. 4.5 Candidate Synonym Ranking and Automation module

(iv) Automated use of Fuzzy set for Information Retrieval

• This module helps in automated search process by the search engine using the techniques like Fuzzy Rule Base, Knowledge Graph etc.

4.5.4 Algorithm for Entity Synonym Discovery

After depicting the process, the algorithm to implement the process is outlined below:

(a) Algorithm: EntitySynonymExtractor(E,QL)

Input: Entity E, Query Log Database (QL)

Output: Ranked list of Entity Synonyms

//Algorithm to find entity synonyms corresponding to input Entity word E

- 1. SERPs = SearchEngine (E) //Submit Query E to interface & extract first 20 pages
- 2. For each $p \in SERPs$
 - 2.1 Pick the candidate entities if the URL returned by search engine is same as the URL already present in the query log. //Let it be {E₁, E₂, E₃,, E_n}
 - 2.2 Extract the URL of page p in order to retrieve context from it.
 - 2.3 Find context using snippets and title related to p. //Let it be $\{C_1, C_2 C_3...C_n\}$

Make combinations of input entity string E and candidate entities obtained

from query log with context obtained in step 2.3. // i.e. $E_iC_i \{E_iC_1, \dots, E_iC_i\}$

 $E_2C_2....E_2C_1, E_2C_2...E_nC_n$ considered as entity synonyms.

- 3. Submit each candidate synonym as a query to the search interface
- 4. newSERPs = SearchEngine(EiCi)
- 5. Refined_Entity_Synonyms=CandidateDiscovery(newSERPs)
- 6. Return(Refined_Entity_Synonyms)
- 7. End.

Algorihm : CandidateDiscovery(newSERPs)

// Entity Candidate Discovery Module

Input: newSERPs (search result pages returned by entity_synonym_extractor)

Output: Refined_Candidate_synonym

- 1. Treat URLs corresponding to new SERPs as Parent URLs denoted as PU's
- For Each URL U_i ∈ PU_i Submit U_i on browser interface and pick 10 sub URLs corresponding to U //call the sub URLs as SPUs

- 2.1 For (Each SPU_i), download page corresponding to URL and name it as Child Document
 - 2.1.1 Extract contexts from each child document
 - 2.1.2 Extract anchor text and URL pair from each child document and store it in a map with attributes as child URL and its corresponding anchor text.

 $2.2 \text{ If } (PU_i == child URL)$

- 2.2.1 Extract anchor text and combine them to the list of candidate synonyms (i.e. CS_i).
- 2.3 If (SPUs == PU_i)
 - 2.3.1 Extract last string from Subparent URL and add it to the list of candidate synonyms (CS_i).
- 3. Make combinations of input entity query string with the contexts obtained in step 2.2.1 and add them to the list of candidate synonyms (CS_k) .
- 4. Now, union all candidate lists obtained in above steps. $Refined_CS = CS_i \cup CS_j \cup CS_k$
- 5. //Ranking Candidate Synonyms
 Retrieve the page counts for *E i.e. NE*For each C*i* ∈ Refined_CS do
 Retrieve the page counts for *E* and C*i i.e. NEci*Retrieve the page counts for C*i i.e. Nci*Compute WebJaccard(*E*, *Ci*) = *NEci* /(*NE* + *NCi NEci*)
 End for

4.6 APPLICATION OF RESULTS

The proposed work is implemented by considering more than 30 user queries randomly selected from the search log of a general web search engine. The algorithm is implemented on Intel Core Duo Processor with 3 GB RAM. Software requirements include installation and setting up the environment for the software like eclipse Java neon and JDK8. Table 4.2 shows the candidate synonyms generated through different approaches including the proposed one. Some example strings are considered for comparison between various approaches. It can be clearly seen that the result set in the proposed approach is much richer than the others. Also Similarity Index (SI) has

been shown with entity synonyms computed on the basis of Web Jaccard coefficient as described in the algorithm.

| Entity string | Candidate synonyms generated through Query Log approach as used in [12] with SI | Candidate synonyms generated through Inbound Anchor Text Approach as used in [15] with SI | Contexts Extracte d from Title & snippets | Candidate synonyms generated through Anchor Text+ Context with SI | Candidate synonyms generated through proposed Methodology (Hybrid of Static & dynamic approaches combined with context) with SI |

The proposed approach can obtain more entity synonyms as compared to conventional approaches which improves the user experience to large extent as seen in Table 4.2. In order to enumerate the effectiveness of the proposed system, precision is used as a standard metric.

The precision is calculated for each approach on the basis of the number of relevant result according to user perspective out of total number relevant results returned using each approach. The users were asked to identify the number of relevant entities in the set of returned candidate entities as shown in Table 4.3 and Fig. 4.6.

While comparing with the other existing approaches as shown in Table 4.2, it can be noticed that the proposed approach can obtain more entity synonyms, which could improve the user experience to a large extent further leads to higher precision.

| | Entity string | Query | Anchor | Anchor+Context | Proposed |

Table 4.3 Number of relevant result over the total number of returned results

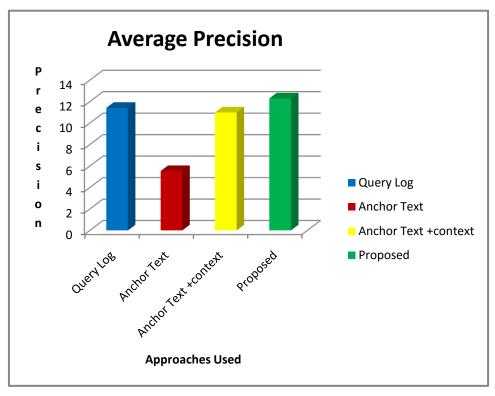

Fig. 4.6 Average Precision for Conventional and Proposed Approach

The proposed work has taken precision as the metric for evaluation of the relative performance. This metric indicates the credibility of the proposed work. We also wanted to include the metrics like Recall & F-measure in the paper, but the repository details of the big search engines and precise details about the actual number of relevant entities in their repositories is also not available. This hindered the computation of Recall and F-Measure.

The graph depicts that precision improves and the results are more meaningful in the case of proposed approch.

4.7 HALL MARK OF THE PROPOSED SCHEME

The primitive approaches use sources like Freebase and Wikipedia to generate entity synonyms for popular entities. These approaches have limited coverage and diversity in the sense that they are able to discover few or no synonyms for less popular entities.

The techniques used in past few years are based on entity source web pages and existing synonyms. Most of these approaches work on offline and structured data to find out entity synonyms, thus, does not cater to the need of dynamic and unstructured nature of WWW.

The proposed approach combines the query log based approach, inbound anchor text and context to find the relevant and accurate candidate entity synonyms. The algorithm focuses on general query logs rather than domain-specific query logs. The query logs can be collected for a specific time frame. The contexts are identified from title and snippet of downloaded web pages which help in finding specialized resultant candidate synonyms helping the user to find better results in minimal time.

To tackle the problem of few or no synonyms for less popular entities, proposed algorithm not only uses inbound anchor text for finding candidate synonyms, but also uses snippets and title of WebPages. The algorithm also introduces a new approach for finding candidate synonyms from trailing part of sub parent URL.

When one talks of entities, it reminds him/her of *Google's Knowledge Graph*. The Knowledge Graph is Google's own database, where all of the data that has been collected from billions of wide web searches is evaluated for relevance. It is a vast graph structured representation containing so many entities and their relationships. It is also a systematic way of putting facts, people and places together and creating interconnected search results that are more accurate and relevant. We have made a small entity knowledge graph for representing entities and their candidate synonyms to the mechanism used by Google to enhance its search engine's results with semantic-search information gathered from a wide variety of sources.

The entity and its candidate synonyms are related by relationship having some similarity value. Thus, this graph can be incorporated and extended to other knowledge bases.

The Knowledge graph for the entity *indiatimes* is shown in Fig. 4.7 and small entity knowledge graph for representing entities and their candidate synonyms is shown in Fig. 4.8.

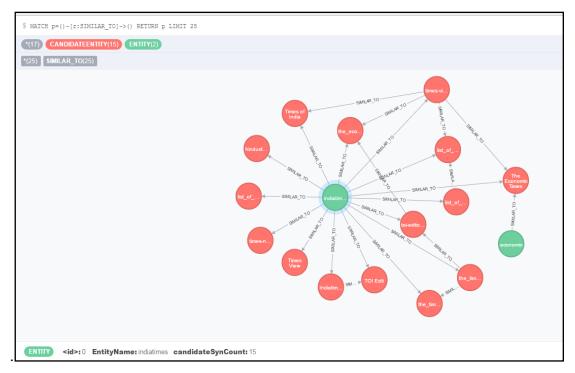

Fig. 4.7 Knowledge graph for the Entity indiatimes

Fig. 4.7 shows the entity and its candidate synonyms where green one represents the original entity and red node represents its candidate synonyms. The strength of relationship between the entity and its synonyms is shown through the weight of the connecting arc.

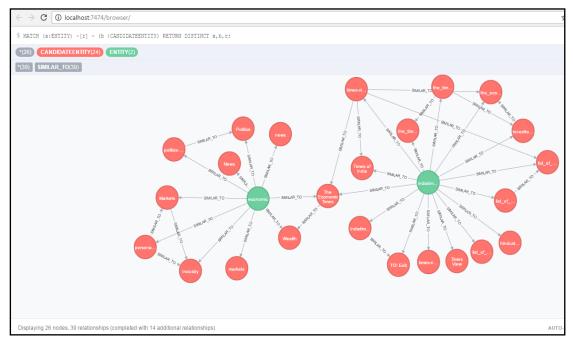

Fig. 4.8 Knowledge graph showing the relationship between two entity synonyms and their candidate synonyms

Fig. 4.8 represents the relationship between two entities and their candidate synonyms. This graph can be utilized by search engine to enhance its search results due to its ability to provide semantic search information for a variety of domains.

4.8 FUZZIFICATION OF RESULTS

The computed index results are normalized to range [0, 1]. This range is used as a domain of discourse to create fuzzy sets expressing the extent of similarity between two words. These fuzzy sets can be used for query auto suggestion, query expansion, query auto replacement etc. thereby enriching the users' search experience in the order as given in the Table 4.4.

| Name of the fuzzy set | Support | Rank | Usage |
|--------------------------|--------------|------|------------------------------|
| Excellent entity synonym | [0.80,1.00] | 1 | Auto Query suggestion, query |
| | | | expansion, query replacement |
| Very Good entity | [0.60, 0.80) | 2 | Auto Query suggestion and |
| Synonym | | | query expansion |
| Good entity Synonym | [0.40, 0.60) | 3 | Auto query suggestion |
| Moderate Entity Synonym | [0.20, 0.40) | 4 | To be used in case of poor |
| | | | precision |
| Poor Entity Synonym | [0.0, 0.20) | 5 | None |

Table 4.4 Creation of Fuzzy Sets

All the above set of generated entity synonyms can be used for various applications like:

- In information retrieval by suggesting the alternative name of the entity for getting more relevant set of documents in response to the user query.
- Creation of Entity Dictionary or Entity Knowledge Graph to enhance search.

4.9 SUMMARY

The proposed technique is scalable and can be implemented for both unstructured and dynamic Web. Moreover, it can be applied on generic as well as domain-dependent content. The results indicate that the mechanism not only provides a rich set of quality synonyms, but also mitigates the polysemy problem to a large extent thereby providing the user with valuable and correct links. The work can be used for automated search process by the search engines using the techniques like Fuzzy Rule Base, Knowledge Graph etc.

The experimental results depict a high precision of the proposed system over other existing search systems. The approach can be used to resolve a query when it contains a named entity and returns smarter and better answers than just a matching of keywords in a query to keywords found in documents that match.

For future work, the candidate synonym set can be used for query reformulation, creation of entity dictionary for web search, named entity recognition in documents, text analytics and to extract information from unstructured data. To extend the work, more parameters can be considered to improve the quality of synonym discovery accuracy.

The next chapter presents the contributions to resolve the concepts used in the query.

CHAPTER V

CONCEPT RESOLUTION FOR FOCUSED AND ENRICHED WEB INFORMATION RETRIEVAL

5.1 INTRODUCTION

The main target of a web search engine is to understand the short piece of query text provided by the user and to give rich and pertinent information. But, the ambiguous, uncertain and inconsistent nature of natural language makes this task quite challenging.

In the previous chapters, we have taken care of *attribute* and *entity* components of the query. In this chapter, the *concept* component of the query is dealt with to direct the query towards more precise understanding of the user needs. In the case of entity and attribute, the query was made rich using the appropriate synonyms of these components. In case of concept, the corresponding query word has to be resolved through the substitution of its appropriate instance(s) using worldly knowledge making it quite a challenging task.

As discussed in the literature survey chapter of this thesis, many attempts have been made to enumerate and aggregate the worldly knowledge in the form of contributions like FreeBase [98], WordNet [97], WikiTaxonomy [112], Cyc [113], YAGO [114], KnowItAll [115], TextRunner [116], OMCS [117], NELL [118] and DBPedia [119] etc. All these contributions are manually curated and the volume of the content is quite low. The number of concepts in the WikiTaxonomy, YAGO and Cyc are between 0.1 to 0.5 million. While in FreeBase, WordNet, DBPedia and NELL, their number is in thousands. These numbers are extremely small, when one takes into account the volume of common sense knowledge associated with this world. In the practical applications requiring wordly knowledge (like web search), these resources prove to be quite inadequate. Therefore, the need has been long felt to develop the huge taxonomies and ontologies based upon the web pages in order to:

• Cover large number of concepts and their instances.

- Cover the heterogeneity and versatility of the web.
- Deal with the probabilistic or partial relationship between the concepts and entities in consideration.

All these works were started from the academic viewpoint and are unable to handle today's demand of worldly knowledge as required by the search engines.

To overcome the above mentioned problems, a project was started to gather the worldly knowledge from the web by Wentao Wu et.al. [121] in association with Microsoft. The details of the collected knowledge are available on the website of the PROBASE [145]. This knowledge contains information about the real world entities and their specific/ generic/ conceptual references with available association count. This chapter proposes and implements an algorithm for concept resolution using PROBASE. Before taking up any further details, let us have a look at the concept resolution problem.

5.2 THE CONCEPT RESOLUTION PROBLEM

When used in the query, a concept has to be substituted for its closest set of instance(s). For example, consider the queries:

Best Universities in Europe Large Software Companies in Asia

Here, it is very hard to characterize and enlist the best universities and to find all the cities in the Europe as the phrase 'best universities' does not have a definite boundary and the word 'Europe' actually implies European cities. The worldly knowledge is too huge to be comprehended and moreover becomes ambiguous, inconsistent and uncertain at many places. Concept resolution means to make appropriate substitutions for the concepts under considerations. It requires:

- Providing the machines/systems the access to large knowledge base related to common sense vocabulary
- Enabling the machines to use this knowledge in an unambiguous manner

Both of these are challenging tasks and can't be executed to perfection. But efforts can be made to accomplish this in a quite appropriate manner. The work proposed in this chapter is an effort in this direction.

5.3 **PROBASE**

PROBASE is a large-scale probabilistic semantic network used for Text Understanding. It is a taxonomy that contains millions of concepts of worldly facts. Unlike traditional taxonomies that treat knowledge as black and white, it uses probabilities to model inconsistent, ambiguous and uncertain information.

The concept space employed by *PROBASE* contains millions of fine-grained, interconnected and probabilistic concepts. For each concept, a number of instances and attributes are present in the *PROBASE*. For example, a concept *company* is connected to instances such as *apple* and *Microsoft* in the knowledge base of *PROBASE*. Moreover, it also scores the concepts and instances, as well as their relationships. This abundant information allows us to build inferencing mechanisms for text analysis and text understanding. Compared with other knowledge bases such as WordNet, Wikipedia, YAGO and Nell, it has two advantages.

- The rich concept information enables interpretation at fine levels. For example, if "China, India", are checked in the PROBASE, then it returns country and Asian country as a top concepts. Given "China, India, Brazil", the top concepts become "developing country, BRIC country, emerging market". Other knowledge bases which were used earlier do not have a fine-grained concept space, nor an inferencing mechanism for the concept, therefore they can at most map these words into the concept of 'country', which is often too general and coarse level for sophisticated text understanding.
- 2. Its probabilistic nature allows one to build inferencing mechanisms which map words in a context to appropriate fine-grained concepts. Moreover, it is taxonomy based upon worldly knowledge, in combination with users' statistics which results in focused and enriched outcomes. The structure of the PROBASE is shown in Table 5.1 and the sample database for the same is shown in Appendix D.

Table 5.1 Structure of PROBASE

| Concept | Instance | Number of Association |
|----------------|---------------|-----------------------|
| Activity | Game | 1871 |
| Game | Chess | 1343 |
| Game | Poker | 601 |
| Bollywood Star | Shahrukh Khan | 15 |

The biggest strength of the PROBASE lies in its two characteristics.

- 1. The taxonomy has been derived from the web, therefore it involves the actually used concepts by the people worldwide involving all sorts of heterogeneity and slang terms.
- 2. The size of the taxonomy is huge and contains very large number of general terms which is much bigger (by one order of magnitude) than its nearest competitors.

5.4 LIMITATIONS OF EARLIER CONTRIBUTIONS

There are many concepts that have been associated with hundred thousand instances making it quite difficult to associate the proper set of instances to the corresponding concept. Efforts in this direction include works of Wang et.al.(2012)[27], Egozi et.al.(April 2012)[21] and Sendhil et.al. (2010)[25]. These works lack depth and operate at quite a surface level. The work proposed by Wang et.al. considers short text as "Bag of Concepts" without taking into consideration the document as a whole. Explicit Semantic Analysis proposed by Egozi et.al. uses relatedness analysis based on Wikipedia but neglects the context of words and cannot exactly determine the desired sense of an ambiguous word. The work proposed by Sendhilet.al. deals with construction of personalized page view graph for small scale search which is limited to an individual only. Fonseca et.al. (2005)[22] generated and organized concept hierarchy from the stored document sets and used it for query expansion purposes with a view to improve precision. Lu et.al. (2017)[23] used TREC-VID 2015 (Multimedia Event Detection System) for handling complex concepts in the user query. Their system detected large number of concepts using pre-trained concept detectors for textual-to-visual relation. Metzler et.al.(2007)[24] proposed a new

mechanism known as 'Latent Concept Expansion (LCE)' for expanding the term concepts for tasks such as query suggestion and query reformulation. Boucenna et.al. (2016)[20] proposed concept-based semantic search for outsourcing the data over cloud after encrypting it.

After studying these contributions, a mechanism has been proposed in this chapter for resolving the concept(s) to its appropriate instances in the presence of available contexts such as IP address, browsing history etc. The motivating factors towards this proposal were as outlined below:

- Manually curated worldly knowledge sources such as NELL, Wikipedia, Freebase, DBPedia are insufficient to fill the requirement of the web search engines.
- There was a need to have a worldly knowledge source with the ability to handle all sort of heterogeneous and multidimensional knowledge pertaining to this world.
- PROBASE is an effort in this direction and is publically accessible on https://concept.research.microsoft.com/Home/Introduction
- Google Humming Bird principle indicates that the users' Geographical Location, Browsing History and other such parameters can be used to cater the interest of individual user.
- In the web pages, a lot of concepts are described in the form of slang terms which are not defined in the online lexical sources e.g. biggie, bigwig, bigwig, heavyweight etc.
- Google has shifted to knowledge graph based search from keyword based search.
- A lot of time is wasted by the search engine if the same query can be interpreted in multiple manners.

5.5 THE PROPOSED CONCEPT RESOLUTION METHOD

Before moving to the proposed work, some adoptable practices are suggested which can help in concept resolution and reduce the burden on the retrieval system. These practices may include:

5.5.1 Textual Practices

Many times a query has multiple interpretations corresponding to different association of words e.g. a query *New York Times Square* can be interpreted into two ways

- New York and Times Square
- New York Times and square.

A textual protocol can be adopted wherein a hyphen can be used to resolve the ambiguity. The above two interpretations can be clarified by writing them in this fashion:

- New-York Times-Square
- New-York-Times Square

5.5.2 Concept Synonym Identification and their Merger

In PROBASE by Wu et.al.(2012)[121], numerous ideas have been distinguished independently but they can be easily merged to expand the likelihood and avoidance of uncertainty. These synonyms, not available in the lexical resources as such, can also be used for the purpose of query expansion and query recommendation. Given below are certain examples

- Celebrity, celeb
- biggie, bigwig, big-wig, heavyweight

Such slang terms though not available in the dictionary can be identified through web exploration and can be manually curated.

Concept resolution is not only helpful for the effective query recommendation, but also helps search engine to find relevant information efficiently. This work focuses on resolving the concepts from the documents to identify ambiguity of the given query, to distinguish the underlying documents based on the meaning of the query and to help web user(s) to get the desired results.

5.5.3 The Proposed Mechanism

A concept-based search query can be a collection of concepts and it can be a combination of concept and entities connected by at least one legitimate relationship(s). The instantiation process can either be direct or indirect depending upon the reality whether the concept directly resolves into the instance or resolves into the instance through a chain of sub-concepts.

It is concluded that not only the concept-concept/concept-entity relationship present in the query can be exploited as the context but even the physical parameters like IP address and the statistical data such as browsing history can also be used to estimate the intended contexts. To guarantee the delivery of intended contexts, the concept of query restructuring and backtracking has been utilized.

Fig. 5.1 demonstrates an outline of proposed concept resolution approach for the goal of web information retrieval. The sketched out system comprises of a set of modules for carrying out various functions. The Concept Identification Module (CIM) identifies the concept term(s) used in the query. This module also recognizes the possible list of entity instances associated with the concept(s) used in the query. To fulfill these tasks, CIM takes the assistance of *PROBASE*.

The extensive Concept-Entity list generated by the CIM module is submitted to the Concept Resolution Module (CRM) for settling the concept(s) to their intended entities.

The CRM gets the huge entity list from CIM related with the concept(s) used in the query. The CRM prunes this list in accordance with the contexts associated with the users' query. These contexts include geographical location with respect to IP address of the client, browsing history of the search engine etc.

The results/outcomes created by the CRM are submitted to Result Processing Module (RPM) which does the final processing, using *PROBASE*, for submission of results to the user.

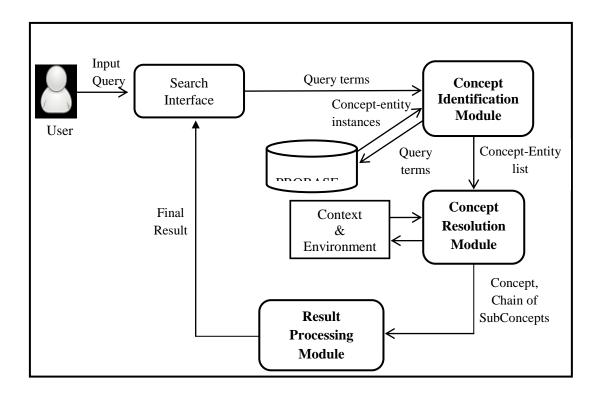

Fig. 5.1 The Proposed Concept Resolution approach for Web Information Retrieval

The working of these modules is taken up in detail in the subsequent sections.

(i) Concept Identification Module(CIM)

Fig. 5.2 demonstrates the working of Concept Identification Module. This module isolates the entities and concepts present in the input query utilizing Concept Entity Relationship File (CERF). The CERF is created by referring *PROBASE* wherein each concept present in the input query is looked for the entities corresponding to the concept are picked up. CERF is populated by isolating concept from entities using tab and all entities related to concepts using comma operator.

All entities from the input query are added to the *entity list* which can be specifically utilized by the Result Processing Module. In order to generate initial concept list, the substrings of concepts are identified that act as synonyms for the concepts present in the input query.

The concepts from the input query and their equivalent words are utilized to generate final concept list using CERF. The final concept list thus generated is passed to the concept resolution module as information.

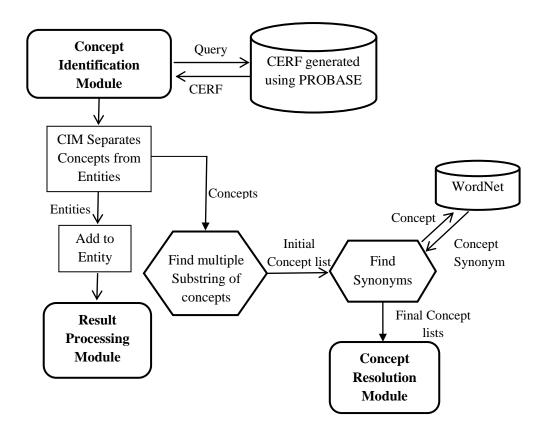

Fig. 5.2 Working of Concept Identification Module

Table 5.2 shows the sample CERF file generated from *PROBASE* which shows relationship between concept and entities simultaneously.

| Table 5.2 The sample CERF file generated from PROBASE that shows relationship between |
|---|
| concept and entities simultaneously. |

| Concepts | Entities belonging to the corresponding Concept(some sample entries) |
|----------------|---|
| bollywood star | Amitabh bachchan, jaya bachchan, shakti kapoor, ranbir kapoor, shahrukh khan, |
| | Katrina kaif, salman khan, shah rukh khan, priyanka chopra, shilpashetty, |
| | kareena kapoor, abhishek bachchan, aishwarya rai, john abraham, sonam kapoor, |
| | sridevi, tabu, shriya saran, vivek oberoi, ranveer singh, aamir khan, dia mirza, |
| | ompuri, preity zinta, hrithik roshan, dilip kumar, akshay kumar, sohail khan, |
| | boney kapoor, saqibsaleem, jaqueline fernandes, deepika padukone etc |
| celebrity | madonna, kimkardashian, rihanna, parishilton, angelinajolie, beyonce, Jennifer |
| | lopez, lady gaga, oprah winfrey, gwynethpaltrow, britney spears, victoria |
| | beckham, jenniferaniston, mileycyrus, jessica alba, katyperry, justinbieber, brad |
| | pitt, lindsaylohan, demi moore, camerondiaz, halle berry, tiger woods, |
| | jessicasimpson, sarahjessica parker, tom cruise, davidbeckham, evalongoria, |
| | kate moss, ellendegeneres, taylor swift, leonardodicaprio, nicolerichie, |

| | juliaroberts, georgeclooney, kanye west, oprah, cher, johnnydepp, |
|------------------|--|
| | cindycrawford, selenagomez, pamela Anderson etc |
| Entities | Concepts belonging to the corresponding Entity(some sample entries) |
| Amitabh Bachchan | |
| Amitaon Dachchan | bollywood star, star, celebrity, bollywood celebrity, bollywood actor, actor, |
| | prominent regional indian artiste, bollywood luminary, big name, stalwart, |
| | person, indian cinema legend, popular actor, high profile indian, famous actor, |
| | top star, bollywood celeb, biggest star, leading man, popular indian celebrity, |
| | indian cinema s stalwart, mainstream bollywood star, famous light skinned |
| | personality, personality, celeb, contemporary star, biggie, dignitary, legendary |
| | figure, eminent personality, bollywood biggie, lauded lead actor, veteran |
| | bollywood star, news report popular indian celeb, big bollywood personality, |
| | established star, film, post, great personality, iconic star, influencer, industry |
| | stalwart, modern icon, legendary actor, bollywood superstar, indian celebrity, |
| | esteemed name etc |
| Salman Khan | star, actor, bollywood star, bollywood actor, bollywood celebrity, superstar, |
| | bollywood superstar, celebrity, bollywood celebrity, co-stars, biggie, a list actor, |
| | personality, film star, indian film heavyweight, popular bollywood actor, |
| | bollywood celeb, a list bollywood star, today s popular actor, visionary well |
| | funded entrepreneur, celeb, famous name, pioneer, big star, famous bollywood |
| | actor, film personality, co star, social entrepreneur, celebrity figure, successful |
| | actor, money making super star, indian actor, hindi star, bollywood personality, |
| | b town celeb, bollywood s biggest name, bollywood biggie, top bollywood star, |
| | mass heroe, leading super star, featuring keynote speaker, top bollywood actor, |
| | famous bollywood film star, bollywoods top star, meagstars, non pashto |
| | speaking pakhtoons, top star, popular bollywood superstar, luminary, popular |
| | actor, a-list actor, top actor, lead actor, bollywood's celebrity, indian mega star, |
| | top film personality, muslim actor, manyabollywood star, bollywood super-stars, |
| | top industry personality, super star etc |

(ii) Concept Resolution Module(CRM)

Fig. 5.3 demonstrates the working of Concept Resolution Module. This module refines the final concept list created through CIM using concept synonym identification and their merger, by tracking IP address, using browsing history, query restructuring and through the use of typical associations. It checks the browsing history to locate the matching concepts, which acts as a source of query suggestion on the search interface for the user to help him/her in rephrasing the query in order to get

the focused and intended results. The module then tracks the IP address of the user (based on geographic location of the user) to produce sub(sub)concept list.

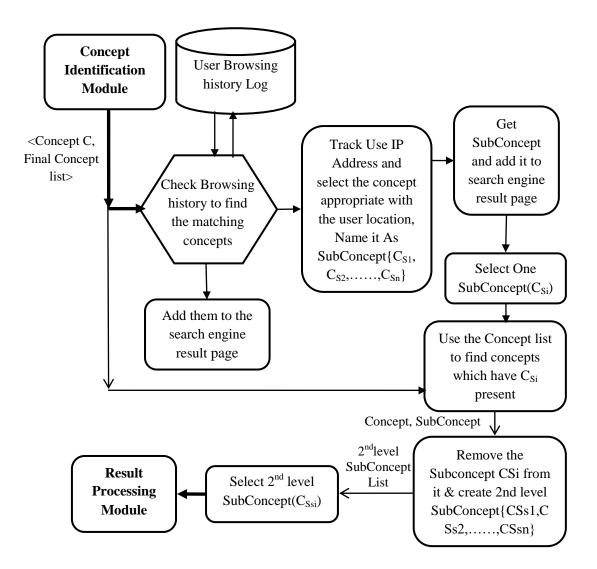

Fig. 5.3 Working of Concept Resolution Module

The motivation behind the IP address usage is to go for the localized orientation of the query because normally one looks for the information identified with his/her local domain. For example, an actor for a U.S citizen is likely to be *hollywood actor* and for a indian citizen is likely to be a *bollywood actor*. For the concept list generated so far the sub-concepts are investigated which can in turn produce new sub-concepts or the entities. The entities generated are put into search engine result pages and the sub-concept investigation continues till they are at last changed over into their associated entities. This completes the concept resolution process.

(iii) Result Processing Module (RPM)

Fig. 5.4 demonstrates the working of Result Processing Module. This module applies backtracking to distinguished entities which belong to majority of the concepts generated in the previous modules. An entity belonging to or having relationship with larger number of concepts is a probable candidate for instantiation. For this purpose ranking given in the *PROBASE* which gives the number of associations between the concept and instance on the web has likewise been utilized. The use of backtracking and number of associations can help in resolving the concept to their intended instances.

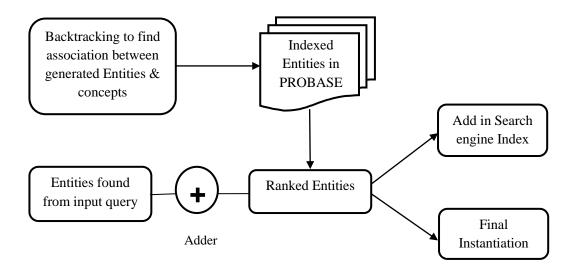

Fig. 5.4 Working of Result Processing Module

The implementation of the proposed system has been done by creating Concept Entity Relationship File (CERF) with the help of PROBASE which is further used to create the concept list through the chain process wherein at each level of the chain, subconcepts and entities are generated and the process continues till no concept is pending for instantiation.

This chain of concepts is then backtracked for creating various query suggestions that can be used by any naïve user to get the desired results.

5.5.4 Example Illustration

The working of RPM can be explained by taking an example query say "Actor"

- Main Query : Actor
- Sub-concept retrieved at level one: Bollywood, Tollywood etc.

In order to move to the next level of concept hierarchy, user can choose any one of the sub-concepts from the available list of sub-concepts. For instance, if user chooses *"Bollywood"*, it would be presented with a list of sub (sub) concepts at the next level

• Acclaimed, Established, Top, Hot etc.

At this level, user can choose any one sub (sub) concept, e.g. "Acclaimed". The RPM module backtracks the chain of concepts found at each level and restructures a new query for getting the proper instantiation for the input query. The chain of concepts can be used to obtain various query suggestions at this level.

{Acclaimed Bollwood Actor, Aamir Kahn, 5}
{Acclaimed Bollwood Actor, Amitabh Bachchan, 4}

Here first argument return the user' query, second argument indicates the instance related to the user's query and third argument indicate the number of association between the concept (first argument) and instance (second argument).

Query Suggestions are:

{Acclaimed Bollwood Actor}
{EstablihedBollwood Actor}
{Top Bollwood Actor}
{Hot Bollwood Actor} etc.

5.5.5 Algorithm for the Proposed Approach (Concept Resolution Algorithm)

The algorithm uses Concept instance knowledge base as an input and creates a concept entity relationship file which is further used to generate the entities corresponding to the concept along with an update browsing history file.

Input : Concept Instance knowledge base using PROBASE, Environmental details (IP address and the geographical location, Browsing history log)

Output : Concept Entity Relationship File (CERF), Refined set of Entities, Updated Browsing history file

Subconcept list= null

2nd level Subconcept list= null

final concept list= null

Step 1. Read Concept Instance Knowledge base

Step 2. For Each distinct Concept C_i from Concept Instance Knowledge Base

- 2.1 Pick the entity corresponding to the concept
- 2.2 Add it to CERF by separating concept from entity using tab and all entities related to concepts using comma.

Step 3. Return CERF.

Step 4. Read the Concept Entity Relationship file and search for Entities present in the query

4.1 Make an arraylist "Entity" with unique entities found

- Step 2. Find the substring of concept found in the input query, Name it C1
 - 4.2 Use C1 to find more concepts from PROBASE and add it to final concept list
- Step 5. Use Browsing history of the user to see any of the matching Concepts previously searched. (Take these Concepts in subconcept List).
- Step 6. If (browsing history==null || no substring match occurs) then use IP address to find the related concepts from the concept list.
- Step 7. Track the IP address of user according to the geographic location of user and add it refine the subconcept list.

7.1 Select one value from the subconcept list

- Step 8. Corresponding to the subconcept selected, See the final Concept list to find Concepts which have the selected subconcept as a Substring.
- Step 9. Select all those Subconcepts.
- Step 10. Remove the subconcept string from these and Display on the Window as 2nd level Subconcepts (Hyperlinks).
- Step 11. Select one hyperlink.

- Step 12. Apply Backtracking to find the Entities related to the concept, subconcept and 2nd levelSubconcept and print it on the window as decreasing values from the CERF file.
- Step 13. Print Entities found directly in the Query.
- Step 14. Update the browsing history file by adding users' past behaviour.

Fig. 5.5 shows the working of the proposed algorithm for the concept popular celebrity as an example and the working of the proposed algorithm for the concept actor is shown in Appendix C.

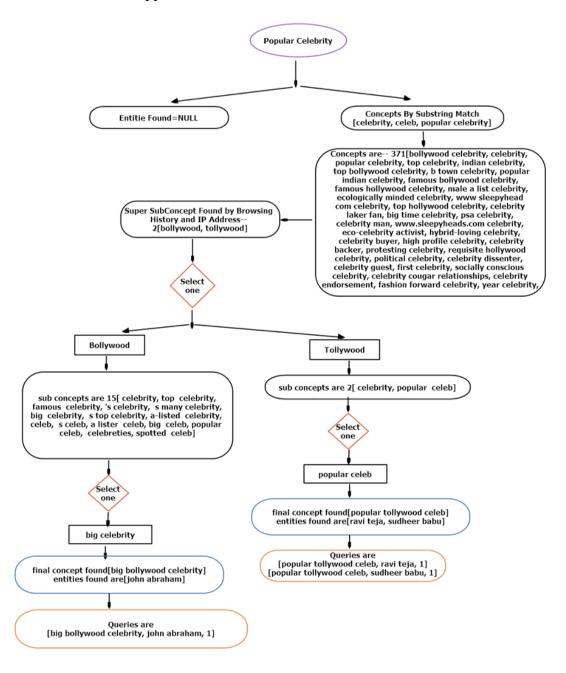

Fig. 5.5 The working of the proposed algorithm for the concept popular celebrity

5.6 IMPLEMENTATION RESULTS

The snapshots of the proposed system for the query *actor* and *bollywood actor* are shown in Appendix C. The results have been compiled using different search engines namely Google, Bing, Yahoo and the proposed system through the execution of the two sets of queries with first set containing 5 queries and second one containing 7. First experiment had 57 users and second one 43. The snapshots of the resulting pages for the two sets of queries on different search engines and the proposed system are shown in Table 5.3 & Table 5.4 and Fig. 5.6 & Fig. 5.7 respectively. In order to quantify the effectiveness of the proposed system, precision is used as a standard metric. The precision is calculated after running query at one level and also when user moves to second level in the concept hierarchy.

| Query | Bing | Yahoo | Google | Proposed |
|-------------------|-------|-------|--------|----------|
| Bollywood_Actor | 36.73 | 38.19 | 42.14 | 61.43 |
| Hollywood_Actor | 38.68 | 25.59 | 30.63 | 40.40 |
| Types_of_Food | 27.73 | 28.04 | 35.19 | 37.60 |
| Italian_Food | 30.30 | 39.46 | 40.35 | 45.61 |
| Music | 38.22 | 34.88 | 40.65 | 48.71 |
| Disaster | 40.10 | 36.63 | 32.49 | 48.59 |
| Automobile | 25.55 | 37.01 | 38.79 | 46.40 |
| Average Precision | 33.90 | 34.26 | 37.18 | 46.96 |

Table 5.3 Precision of various search engines & proposed system for one level query

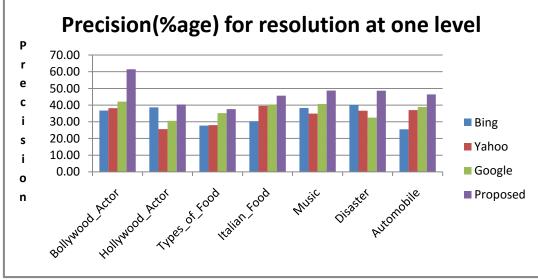

Fig. 5.6 Precision showing Resolution for one level queries

The experiment involved running a set of queries on the proposed system and the commonly available search engines. The users were asked to identify the number of relevant query suggestions made by various search engines and the proposed system. It can be observed from Fig. 5.6 and Fig. 5.7 that precision improves after exploring one more level in the concept herarchy and the results are more meaningful in the case of proposed approch i.e. precision improves when one moves towards specialized concepts in the concept hierarchy.

Queries Bing Yahoo Google Proposed 34.73 40.19 46.14 61.43 Actor Food 25.73 30.04 35.19 40.60 Music 38.22 34.88 42.65 48.71 Disaster 42.10 52.63 38.49 59.59 37.01 40.79 57.40 Automobile 55.55 Average Precision 39.27 38.95 40.65 53.55

Table 5.4 Precision of various search engines & Proposed system for two level query

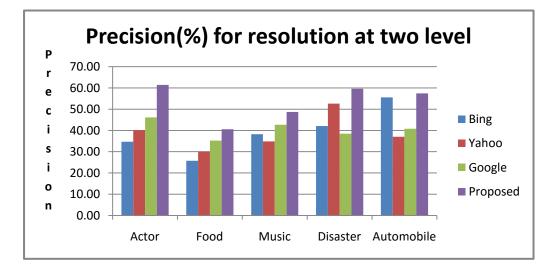

Fig. 5.7 Precision showing Resolution for two level queries

In the last phase of the system, a new query is presented to the user as a query suggestion which is having the most appropriate sub-concept corresponding to the concept present in the input query. This allows users to frame a proper search query

with the knowledge of domain terminology which will help the search engine to get the desired results.

Fig. 5.7 depicts the precision of proposed system and other search engines for various queries to measure the accuracy using traditional keyword search. It is clearly distinguishable that proposed system depicts cutting-edge results over keyword based search.

5.7 SUMMARY

The chapter presented the details about a novel approach of concept based information retrieval using concept resolution on the basis of sub-concept identification, IP address location, browsing history of the user, typical association and query rephrasing & backtracking. For the requisite worldly knowledge, the *PROBASE* has been used. This requirement has its own overhead which cannot be eradicated. The only possible alternative is to reduce the impact of this overhead on the search time by running the parallel threads to explore the worldly knowledge source in the faster manner. The working model for the same will be able to resolve the concepts to quite large extent enabling the search engine to provide the user with the meaningful and relevant results. A method is proposed for the reformulation of a query by rewriting the original query to better match the user needs such that precision and recall can be improved without affecting the original intent of the user. In fact, the experimental results depict a high precision of the proposed system over other existing search systems. The algorithm offers a mechanism which provides large scale generalization created by the voluminous worldly knowledge to the specific requirement of the user. The proposed system is simple and is able to provide ease to web users to build a proper search query with the knowledge domain terminology which will help search engine to get the desired results.

Next chapter presents the results thus obtained and their detailed discussion.

CHAPTER VI

CONCLUSION AND FUTURE ENHANCEMENT OF PROPOSED WORK

6.1 CONCLUSION

As the volume of information on the WWW continues to increase on daily basis, almost all the information available in almost all the domains is accessible on it in today's scenario. Not only the volume of information is increasing on continuous basis, but more and more heterogeneity is also becoming the part of it as the contributions are coming from around the world involving linguistic, cultural and geographical differences.

The low cost of data usage and anywhere/ anytime availability of information has proved to be a motivating factor for seeking the information from the web instead of other resources like encyclopaedia and libraries. But, the crux of the situation is:

Query is still a very short piece of text.

Exploring such a gigantic volume of information with the query text is becoming more and more challenging task for the search engines. So, there is a need to create different semantically similar versions of the query to cover the entire spectrum of the information sought. This can be done by finding out the semantically similar versions of the words used in the query (word synonyms) and similar names of entities (entity synonyms) which are compatible worldwide and have the capability to deal with the heterogeneity of the web. Also a concept used in the query must be translated to its appropriate set of instances in the light of worldly information. The work carried out in this thesis is an effort in this direction.

A summarization of the carried out work is as follows:

• The work presents an efficient and effective approach for finding semantic similarity between words depending upon their contexts. The outcome of the work includes context set identification for a word and computation of an

index indicating the extent of semantic similarity between a pair of words. The computed index has been fuzzified into a FRB for the purpose of automation which can be further utilized by the existing web search engines and other such applications. Thus, a modified lexical resource has been proposed along with several query replacement techniques in order to get efficient and quality search engine results pages.

- It proposes and implements a credible method to generate a rich set of global entity synonyms for the commonly used entities using web data wherein the availability of the candidate data is not a priori requirement. The work also proposes an index to assess the quality of entity synonyms generated which is further normalized and fuzzified for implementing automated search. It also tackles the problem of few or no synonyms for less popular entities. The proposed technique is scalable and can be implemented for both unstructured and dynamic Web.
- It enables search engines to associate the concept used in query with appropriate set of instances using a worldly knowledge source called PROBASE in the light of the factors like user's browsing history, geographical location and IP address etc.
- It also discusses the textual practices for phrase sense disambiguation for meaningful web search.
- The proposed work deals with poor quality queries by finding most appropriate replacement of original query. Thus, it helps to discover relevant information as per user query.

It is hopeful that the proposed work shall be immense help to the information and computer science professionals.

6.2 FUTURE ENHANCEMENT

The work can be further extended by devising more refined methods which are able to take up the heterogeneity of the web in the simplistic and convincing manner and construct effective rephrased queries which cover the larger spectrum of the information. Also, more and more sources of worldly knowledge sources can be created and utilized to ensure the more effective translation of the concept to its appropriate set of instances.

Some of the possible extensions and issues that could be further explored in the near future are as follows:

- The semantic search system proposed in this dissertation can be extended to serve complex user queries, besides serving topical and informational queries.
- The work can be extended by the inclusion of more parameters and application of sophisticated techniques.
- The proposed method works on query elements. The query segmentation process has been left for the search engine and can be worked on in future.

APPENDIX-A

The methodology proposed is Chapter III is corpus centric (starting from the corpus analysis to build the Next Generation Lexical Resource using contexts from corpuses). Four different corpuses are used to extract the set of contexts for both the input query word and its synonyms obtained from the lexical resource. These corpuses can handle complex queries typically in two or three seconds. Finally, the relational database design of these corpuses allows a range of queries that we believe is unmatched by any other architecture for large corpora. In order to search the context, input word (adjective) is used along with an asterisk (i.e. beautiful*) on the interface of the online available corpus. The snapshot is shown below in Fig. A.1.

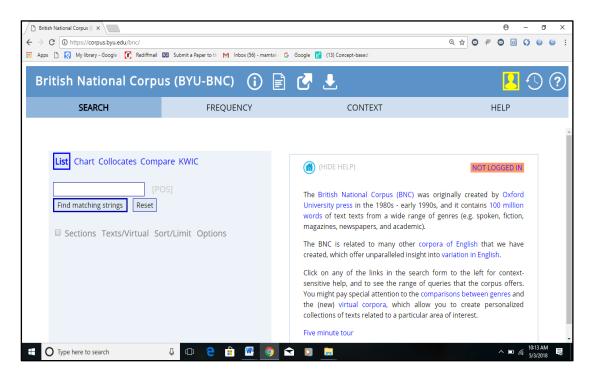

Fig. A.1 Snapshot of the British National Corpus (BNC)

In Fig. A.2 area A depicts the various contexts of word "beautiful" extracted from corpus BNC and area B depicts its frequency in the corpus.

Fig. A.8 Snapshot of the GLOWBE Corpus for the word Pretty

These corpuses are publically available which anyone can use for free. The reason for choosing these four corpuses is their ability to store data belonging to multiple domains.

APPENDIX-B

Entity synonym finding technique based on query log and web data discussed in Section 4.5 of chapter IV is implemented. The proposed technique is implemented as a standalone tool. AOL search data release (20M queries, 650K users, 3 months) is used to extract the entity synonyms from static web and then dynamic web is also explored to get the rich and relevant set of entity synonyms.

Some minimum hardware, software and database requirements are essential for efficiently working of the proposed approach. The minimum system requirement includes:

(i) Hardware Requirements:

- Processor: Intel Core 2 Duo CPU T5470 @1.60Ghz
- Ram: 3 GB
- System: 32 bit/64 bit //If windows is of 32 bit then all software listed below should be of 32 bit.
- Fast internet connectivity for getting better and fast results

(ii) Software Requirements:

Software requirements include installation and setting up the environment for the following software:

- Eclipse Java Neon as it includes Maven dependency implicitly; for other eclipse version, maven set up need to be done.
- Java 8
- Jre8/Jdk 8 (setting up the environment variables of jre and jdk)
- Mysql server
- Mysql workbench
- Neo4j community edition for making graph database of entities
- Stanfordcorenlp parser and lemmatizer dependencies or jar files for pre processing task
- Various other dependencies like Mysql connector, Jsoup, common-lang3, common-codec etc are needed for running the entire project.

(iii) Database Requirements:

• Setting a local database connection and schema on Mysql workbench

- AOL query logs
- Addition of these AOL query logs to tables for processing the results

Query log is used to obtain the basic set of entity synonyms by matching the URLs returned on search interface with the URLs present in Query Log. A snapshot of the sample query log containing adequate amount of queries is shown in Fig. B.1 and B.2.

Fig. B.4 Snapshot of different URLs clicked for the query Times of India

In order to find the candidate entity synonyms from the query log, the user is first asked to enter the input query as an entity onto the search interface. The step is required to initiate the implementation of the proposed work. Then, the next step is to match the URLs returned by the search engine with the URL present in the query log to obtain the first set of candidate synonyms. Fig. B.5 shows the snapshot of the implementation work to obtain the entity synonyms from query log.

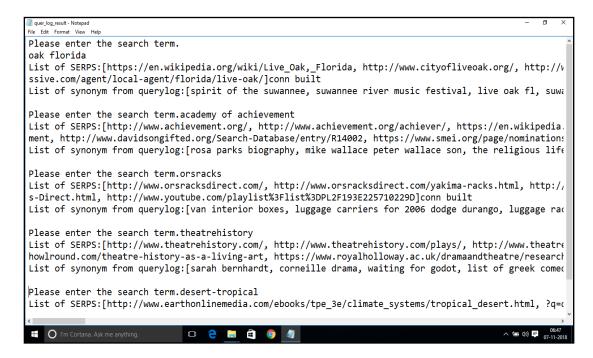

Fig. B.5 Results to find first set of entity synonyms using Query Log

The set of candidate entity synonyms are then presented back to user as shown in Fig. B.5. These basic set of candidate synonyms are then used to obtain the rich and relevant set of entity synonyms with similarity index. The snapshots are shown in Fig. B.6 & Fig. B.7. Similarity measure or similarity function is used to measure the extent of similarity between the input entity and the candidate synonyms extracted from the database. The proposed works uses WebJaccard similarity measure to accurately measure the relevance between input entity and candidate synonym, which is further used to rank the candidate synonyms.

Fig. B.6 depicts the list of entity synonyms obtained using anchor text.

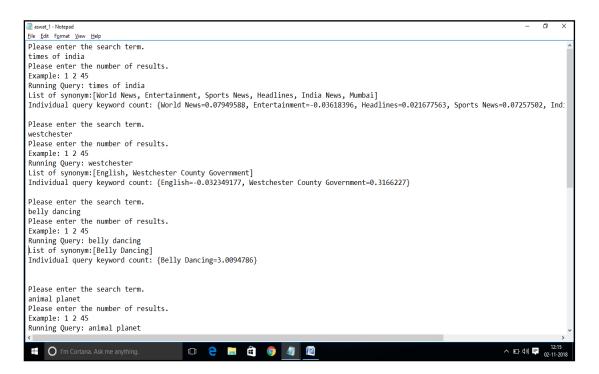

Fig. B.6 Result list of entity synonyms obtained using Anchor Text

Fig. B.7 & Fig. B.8 depicts the list of entity synonyms obtained using *inbound anchor text* along with the context along with the extent of similarity.

Fig. B.8 Results of the Anchor Text + Context to find entity synonyms

Fig. B.9- B.11 shows the entity synonyms obtained after implemented the proposed work. It can be noted from the implementation results of the proposed system that it is able to find more optimized set of entity synonyms both in terms of quality and quantity.

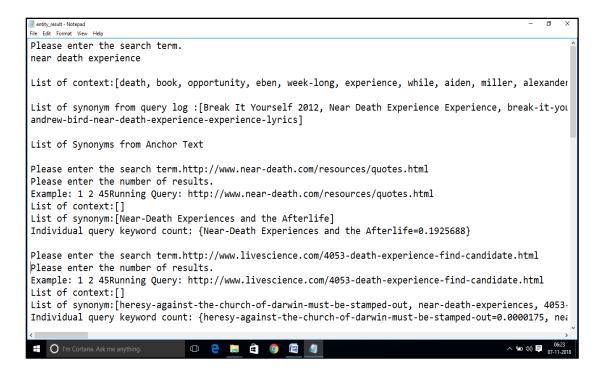

Fig. B.9 Results of the Proposed work to find entity synonyms

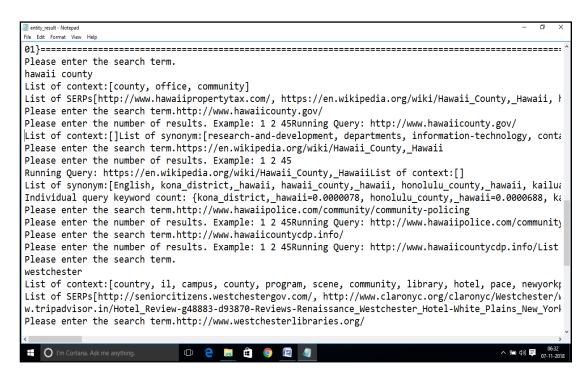

Fig. B.10 More Results of the proposed work to find entity synonyms

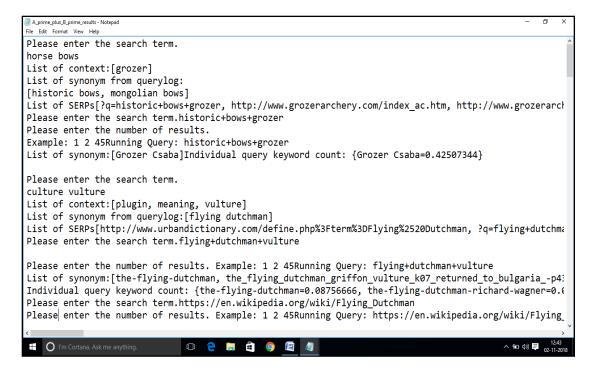

Fig. B.11 More Results of the proposed work to find entity synonyms

Table 4.2 of Chapter IV shows the comparison between the conventional and the proposed approach.

APPENDIX-C

Few snapshots of the data set for concept instance file are shown in Fig. C.1 to C.8. It contains 2.7 million concepts which are collected from 1.68 billion web pages. It contains concepts of worldly facts that human being has formed in their mind. The main reason for using this knowledge source is due to the fact that 85% of the searches contain concepts and/or instances that exist in PROBASE.

Fig. C.8 Snapshot when the keyword *celebrity* is filtered in knowledge base

The working of the proposed algorithm for the concept actor is shown in Fig. C.1.

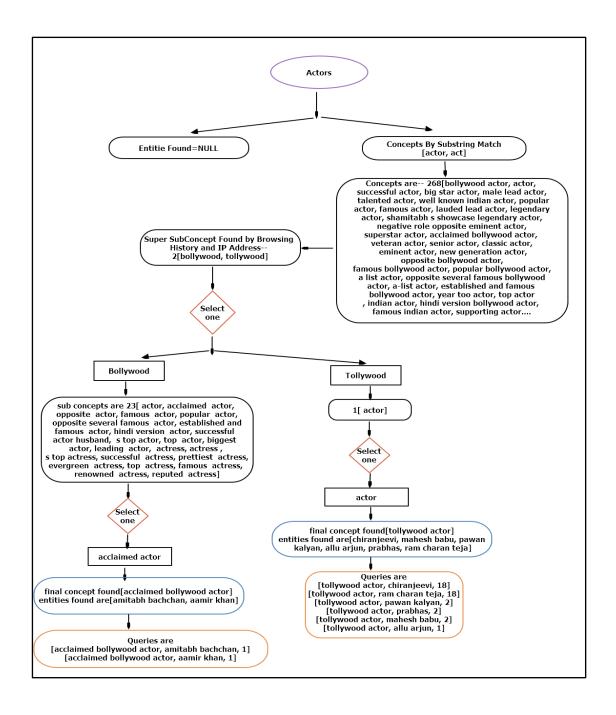

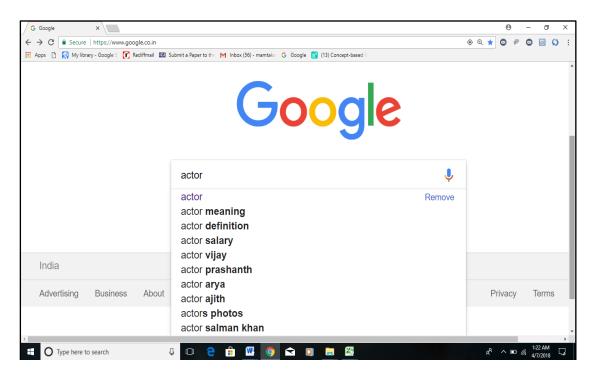

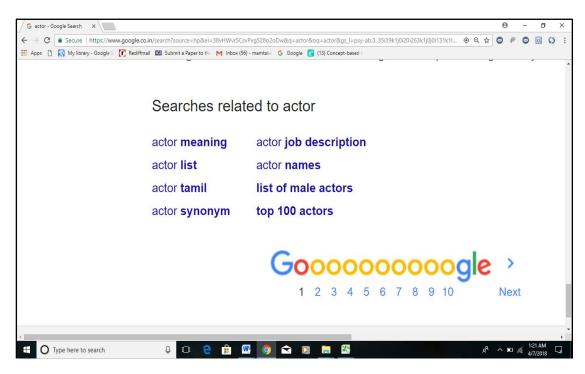

Fig. C.9 Working of the algorithm for the query Actors

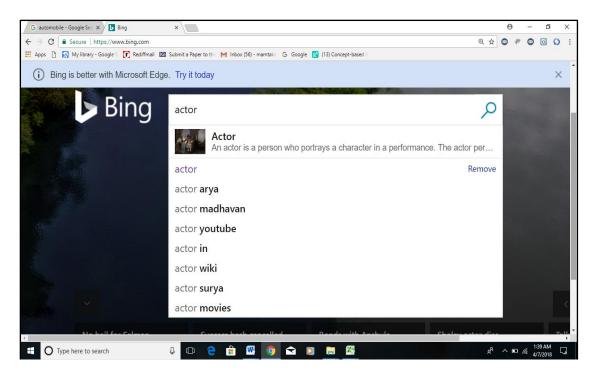

Query suggestion technique discussed in Section 5.5 of Chapter V is implemented using JAVA eclipse neon. At the front end, a web based project is developed which can be used by anyuser, anywhere to run the implementation of the proposed system. we use PROBASE as a back end tool to extract instances corresponding to the concept. Note that due to privacy concerns we cannot share all the details of the coding. The results of the proposed system has been compared with the topmost search engines such as Google, Bing and Yahoo. The snapshots of the proposed system for the query *actor* and *bollywood actor* are shown in Fig. C.10- C.23.

A fragment of Concept Instance File (PROBASE) containing adequate amount of entries is shown in Table C 1.1. The table has three columns. First and second column indicates concept, instance/ entity respectively and third column indicates the number of associations between concept and its corresponding instance.

| Concept | Entity/ Instance | Number of association |

BRIEF PROFILE OF THE RESEARCH SCHOLAR

Mamta Kathuria has received her Masters in Computer Application from Kurukshetra University, Kurukshetra in the year 2005 and M. Tech. in Computer Engineering from Maharishi Dayanand University, Rohtak in the year 2008 respectively. She is pursuing her Ph.D in Computer Engineering from YMCA University of Science and Technology, Faridabad. She is currently working as an Assistant Professor in YMCA University of Science & Technology, Faridabad and has eleven years of experience. She has published more than twenty research papers in various international journals and conferences. Her areas of interest are search engines, Web Mining and Fuzzy Logic.

A FUZZY LOGIC BASED FRAMEWORK FOR RELEVANT INFORMATION RETRIEVAL

(SUMMARY)

1.1 GENERAL

The World Wide Web (WWW)[1] is a gigantic repository that keeps information related to almost every domain of knowledge accessible everywhere on anytime basis. The massive size, continuous update of the information, heterogeneity on the basis of various factors like linguistics, geographical location, cultures and other parameters make the task of information retrieval quite complex and challenging.

Though the performance of search engines in today's scenario is quite impressive yet there has been the ever felt need for novel mechanisms for accomplishing expectations of the users who are seeking the rich set of relevant results for their submitted queries.

The basic reasons for the inability of the search engines to provide the relevant results which are not up to expected levels are as follows:

- Query is a very short piece of text in natural language and successful retrieval is very much dependent of the intent of the user behind the query.
- Natural language is ambiguous and affects the relevance/quality of search results returned by the search engine.
- Users may use slang terms which are not as such part of the language.
- The reference in the query may be conceptual requiring proper instantiation.
- The reference in the query may refer to an entity recognizable by different names.
- Current Lexical resources are unable to cover the heterogeneity of the web.
- Web is continuously updating.

All these issues need to be addressed for getting the rich and relevant information from the web. The literature contains a lot of work in this regard, the study of which motivated us to carry out the work briefly described in this summary.

1.2 PROBLEM IDENTIFICATION

To understand the ongoing work being carried out to overcome the above mentioned problems, a lot of literature was were studied. It was felt that there is an ample opportunity to carry out further research to ensure the rich and relevant information by working on various components of the query. The main focus of the work done is to improve the query used by the user for getting relevant and useful results. It has been observed that queries to search engines on the Web are usually short, imprecise and ambiguous. They do not contain enough signals for statistical inference and do not provide satisfactory information for an effective selection of relevant documents. To find the relevant documents, matching is done purely on the basis of occurrence of keyword or expression in the document. But, it is not always necessary that a document containing a word with high frequency will be relevant. Thus, it can be seen that the relevance computation is done purely on the basis of occurrence of keywords in content; it does not consider the context of keywords. The proposed work in this thesis finds the equivalent word of query in the presence of contexts. So, the work paves the attention to identify the different categories of the query.

The literature survey has shown that the basic constituents of a query can be classified into four categories: *Keywords, Attributes, Entities and Concepts*.

- *Keywords* are non-trivial words which carry the essence of the query. The keywords make the query meaningful and are the major guiding factors for relevant information retrieval to be carried out by the search engines.
- (ii) Entities are persons/places/objects referred in the query which have distinct and independent existence. Different users may refer to the same entity in different manners. For example, the newspaper The Times of India may also be referred to as TOI. A search engine must be able to handle these multiple versions of the references used in the query. These multiple references have been referred to as entity synonyms in the work [2, 3]. Creation of appropriate set of entity synonyms for a given entity is

also a major requirement for relevant and rich information retrieval. Various contributions in this field are available in [2-10].

- (iii) Attributes are the words which define the features/ characteristics of entities and keywords used in the query. To enrich the search process, a web search engine may create multiple versions of the same query by using the appropriate set of synonyms of the attributes used in the query and create an index to access the quality of the synonym generated. Various contributions in this field are available in [11-19].
- (iv) A Concept in the query is a word which refers to a broad category of objects in generic manner. For example, in the query "good actors in India", Good actors is a concept. A concept referred in query has to be translated to its closest set of instance(s). Handling of the concept is the most challenging task for the search engine as its resolution requires the understanding and usage of worldly knowledge. The instantiation of a concept can vary depending upon the local & global contexts. The hardest part of the query expansion is to find the appropriate instantiation for the concept used in the query as per the requirement of the user. Various contributions in this field are available in [20-31].

After going through the literature, following inferences were drawn:

- Keywords are the essential part of the query and should not be disturbed/modified/altered.
- Lexical resources are unable to provide the requisite set of synonyms for the words used in the query owing to the widespread and heterogeneous nature of the web. So, there is a need to find out global mechanisms for creating the set of synonyms which truly cover the heterogeneity of the web.
- Alternative references to entities (also known as entity synonyms) are not at all supported by the lexical resources. The only way one can find out the entity synonyms is through web exploration and analysis of web logs.
- Conceptual references need to be translated into their worthy instances which are quite a challenging task as it requires worldly knowledge.

After exploring all this literature, we were in a position to set the objectives of the proposed work.

1.3 OBJECTIVES

As the amount of information on the web is increasing and changing rapidly without any control, existing search methodologies do not fit best to find the required information. Therefore, the need arises to devise some new methodologies so that relevant data can be retrieved.

In the light of the above motivational factors, the main objective of the proposed work is to improve the performance of search engines using query recommendation so that relevant information can be retrieved from WWW.

Following objectives were set for the proposed work:

- a) To devise a mechanism to search synonyms of an attribute word of the query using huge document repositories.
- b) To devise a mechanism to search rich set of entity synonyms for an entity using static and dynamic web.
- c) To design an index to assess the quality of synonyms as two synonyms of the same word can't have same intensity.
- d) To devise a mechanism to translate a concept to its intended instances using worldly knowledge source.
- e) To devise a mechanism for automated usage of identified set of synonyms to be utilized by the machine.

1.4 PROBLEM DEFINITION

To ensure relevant web search through query rephrasing or expansion using:

- rich set of identified synonyms for the entities and the attributes used in the query
- appropriate instances for the concepts present in the query

and to devise novel mechanisms for the purpose.

1.5 ACCOMPLISHMENTS

Following accomplishments were made during this work:

- a) A mechanism to search synonyms of an attribute word on the basis of the context identification using multiple corpora was proposed and implemented. The method is quite an improvement over the existing methods based on page count and snippets. The proposed work is used in web search and other applications such as:
 - i) Enrichment of lexical Resources
 - ii) Word Sense Disambiguation
 - iii) Automated query expansion for web search
- b) A mechanism to generate rich set of entity synonyms for an entity using query log and anchor text was proposed and implemented. The technique is scalable and can be implemented for both unstructured and dynamic web. The work can be used for automated search process by the search engine using the techniques like Fuzzy Rule Base and Knowledge Graph etc. The basic outcomes are:
 - i) Query expansion for enriched search without losing the relevance
 - ii) Improved Search Relevance
 - iii) Query Auto Suggestion
 - iv) Creation of Entity Knowledge Graph
- c) For both of the above mechanisms, an index was created to assess the quality of synonyms. The index was fuzzified and a Fuzzy Rule Base (FRB) was created for automated deployment of synonyms for various purposes. The proposed system enables to make the user to choose soft decision based on the extent of semantic similarity by the use of fuzzy logic rather than rejection in case of hard decision. The outcomes achieved are:
 - i) Fuzzy Rule Base creation
 - Use of Fuzzy Rule Base for the purpose of automation by choosing the semantically similar word based upon the similarity index
- d) A mechanism to translate a concept to its intended instances was proposed and implemented using PROBASE (the largest available worldly knowledge source) [32]. The approach can be considered as a mechanism from large

scale generalization created by the voluminous worldly knowledge to the specific requirement of the user. Outcomes achieved are:

- (a) Supporting the machine intelligence with real world knowledge.
- (b) Enrich the web search by moving from conceptualization to instantiation.

1.6 CONTRIBUTION

The proposed work contributes towards query expansion and resolution in existing search engines. It has been observed that for finding the relevant documents in response to user query, the traditional methods used by search engines are not a correct choice because they return documents in response to query keywords given by the user without considering the semantic aspect of a query.

In this work, specifically, a novel architecture for resolving different types of queries has been proposed and implemented. The proposed design is shown in Fig. 1. It takes the query as an input from the users and returns the recommendations for the proper replacement of the original input query.

The major functional components of the framework are given below:

a) Procedure for finding semantically similar word

The main objective of the work is to propose a synonym resolution method based upon the immediate context in various corpora. The search engines, if do not take into account the context of a query and unseeingly use the online lexical resources, may lead to fetching of large number of undesired pages which are otherwise not essential. To defeat this weakness, it is required that query be expanded through meaningful semantic expressions using context set. Keeping this need in view, this module focuses on a novel approach which tunes the lexical resources wherein the derived synonyms of a word are also provided with their applicable context. The outcome of the work includes context set identification for a word and computation of an index indicating the extent of semantic similarity between a pair of words.

The computed index has been fuzzified into a Fuzzy Rule Base for the purpose of automation and its usage into the web search engines and other such applications.

To ensure the unbiasedness of the approach, multiple corpora with wide range of genres and with each one containing huge set of documents have been taken up. The similarity index has been computed on the basis of commonality of the contexts. Various benchmark indices have been used to find the similarity index and the results have been normalized. The results obtained have been compared with a standard toolkit (UMBC) for the purpose of authentication. The obtained results have been used for the enrichment of lexical resources.

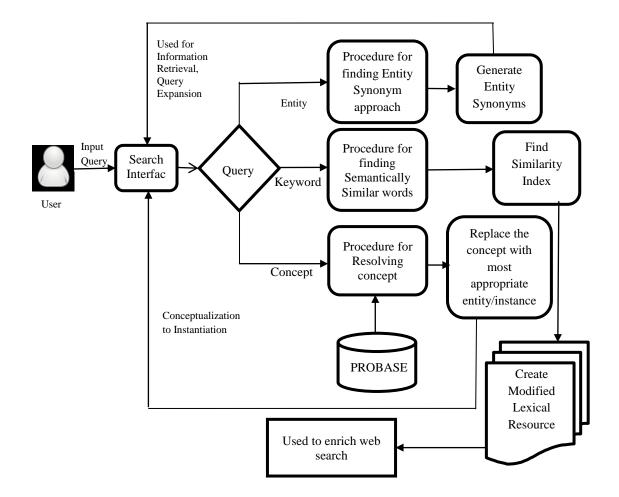

Fig 1: A Framework for Relevant Information Retrieval

b) Procedure for finding Entity Synonym

The proposed work involves the iterative use of Search Engine Result Pages (SERPs), extraction of context from the URL, query logs and extraction of anchor text. The process begins with the issuance of query by the web user on any search engine interface. The search engine receives the query and returns result pages referred to as SERPs. In the proposed approach, the SERPs are searched in the query log to obtain the candidate synonyms. The title and snippets of the URLs of these SERPs are used to obtain the contexts. A new query is then issued to the search interface using a combination of a candidate synonym and the context related to an entity to obtain a new set of SERPs. An algorithm based on *Inbound Anchor Text* is then applied to extract more and more possible synonyms. The URLs obtained are collected to form parent URLs. Next, these parents URLs are further treated as input to generate sub parent URLs (SPUs). Then, each page of SPU is visited and all the (anchor text, link) pairs are collected in a hash map as a set of child URLs. Finally, each of these child URLs are compared with the parent URL and when exact match gets found, the corresponding anchor text is saved in another map. The title of the SPU and snippets are also used to explore more candidate synonyms.

After getting the candidate synonyms, similarity index is computed between the actual entity word and the candidate synonyms using *Web Jaccard* method. The index values obtained are then normalized between the range [0, 1]. Taking the normalized fuzzy value as the outline criteria, fuzzy sets are defined to express the quality of synonyms linguistically. These fuzzy sets are then used in Fuzzy Rule Base (FRB) for the automated application of entity synonyms in the web search process.

Entity synonyms generated through the proposed method have an edge over prevailing mechanisms, as it provides:

- More relevant set of entity synonyms (both in terms of quantity and quality)
- An index to access the quality of generated entity synonyms.
- Fuzzification of the Index for the purpose of automation.

The work will contribute to web-search in following ways:

- Improved search relevance
- Improved user experience
- Query auto suggestion
- Creation of entity dictionary
- Meaningful query expansion for the queries involving entities.

c) Procedure for Concept Resolution

The outlined framework consists of a set of modules for carrying out various functions. The very first module isolates the entities and concepts present in the input query by utilizing Concept Entity Relationship File (CERF). The CERF is created by referring PROBASE wherein each concept present in the input query is looked for the entities corresponding to the concept are picked up. CERF is populated by isolating concept from entities using tab and all entities related to concepts using comma operator. A concept list is thus generated by taking the substrings of concept and synonym of the concept present in the input query.

The concept list so obtained is then refined using concept synonym identification and their merger, by tracking IP address, using browsing history, query restructuring and through the use of typical associations. It checks the browsing history to locate the matching concepts, which acts as a source of query suggestion on the search interface for the user to help him/her in rephrasing the query in order to get the focused and intended results. The module then tracks the IP address of the user (based on geographic location of the user) to produce sub(sub)concept list.

The motivation behind the IP address usage is to go for the localized orientation of the query because normally one looks for the information identified with his/her local domain. For example, an actor for a U.S citizen is likely to be *hollywood actor* and for a indian citizen is likely to be a *bollywood actor*. For the concept list generated so far the sub-concepts are investigated which can in turn produce new sub-concepts or the entities. The entities generated are put into search engine result pages and the sub-concept investigation continues till they are at last changed over into their associated entities. This completes the concept resolution process.

After the concept resolution process, backtracking is used to distinguished entities which belong to majority of the concepts generated in the previous modules. An entity belonging to or having relationship with larger number of concepts is a probable candidate for instantiation. For this purpose ranking given in the *PROBASE* which gives the number of associations between the concept and instance on the web has likewise been utilized. The use of backtracking and number of associations can help in resolving the concept to their intended instances.

The algorithm offers a mechanism which provides large scale generalization created by the voluminous worldly knowledge to the specific requirement of the user. The proposed system is simple and is able to provide ease to web users to build a proper search query with the knowledge domain terminology which will help search engine to get the desired results.

1.7 CONCLUSION

As the volume of information on the WWW continues to increase on daily basis, almost all the information available in almost all the domains is accessible on it in today's scenario. Not only the volume of information is increasing on continuous basis, but more and more heterogeneity is also becoming the part of it as the contributions are coming from around the world involving linguistic, cultural and geographical differences.

The low cost of data usage and anywhere/ anytime availability of information has proved to be a motivating factor for seeking the information from the web instead of other resources like encyclopedia and libraries. But, the crux of the situation is:

Query is still a very short piece of text.

Exploring such a gigantic volume of information with the query text is becoming more and more challenging task for the search engines. So, there is a need to create different semantically similar versions of the query to cover the entire spectrum of the information sought. This can be done by finding out the semantically similar versions of the words used in the query (word synonyms) and similar names of entities (entity synonyms) which are compatible worldwide and have the capability to deal with the heterogeneity of the web. Also a concept used in the query must be translated to its appropriate set of instances in the light of worldly information. The work carried out in this thesis is an effort in this direction.

A summarization of the carried out work is as follows:

• The proposed technique is used to overcome the problems of synonymy and polysemy in the information retrieval field, by finding the semantically similar words with respect to the input query.

- The fuzzy sets created in the proposed work can be used for intelligent decision making by creating a Fuzzy Rule Base (FRB) that can be run on an appropriate fuzzy inference engine.
- It proposes and implements a credible method to generate a rich set of global entity synonyms for the commonly used entities using web data wherein the availability of the candidate data is not a priori requirement.
- Entity synonym finding technique is scalable and can be implemented for both unstructured and dynamic web.
- In information retrieval by suggesting the alternative name of the entity for getting more relevant set of documents in response to the user query.
- It helps to create Entity Dictionary or Entity Knowledge Graph that can be used to enhance search.
- It enables search engines to associate the concept used in query with appropriate set of instances using a worldly knowledge source called PROBASE in the light of the factors like user's browsing history, geographical location and IP address etc.
- It also discusses the textual practices for phrase sense disambiguation for meaningful web search.
- The proposed work deals with poor quality queries by finding most appropriate replacement of original query. Thus, it helps to discover relevant information as per user query.

It is hopeful that the proposed work shall be immense help to the information and computer science professionals.

1.8 FUTURE ENHANCEMENT

The work can be further extended by devising more refined methods which are able to take up the heterogeneity of the web in the simplistic and convincing manner and construct effective rephrased queries which cover the larger spectrum of the information. Also, more and more sources of worldly knowledge sources can be created and utilized to ensure the more effective translation of the concept to its appropriate set of instances. Some of the possible extensions and issues that could be further explored in the near future are as follows:

- The automated search system based upon semantic similarity proposed in this dissertation can be extended to serve complex user queries, besides serving topical and informational queries.
- The work can be extended by the inclusion of more parameters and application of sophisticated techniques.
- The proposed method works on query elements. The query segmentation process has been left for the search engine and can be worked on in future.

1.9 ORGANIZATION OF THE THESIS

The thesis has been organized as follows:

Chapter II: Literature Survey: This chapter contains a discussion on the available work related to search engine evolution, semantic similarity between words, entities and concept based web search. Based on the literature survey on each topic, the problems and challenges have been identified and discussed in brief. These problems and challenges form the basis for the work carried out.

Chapter III: Synonym Resolution for Attribute Component in Query: This chapter talks about the proposed semantic similarity technique and its implementation for attributes component present in the query. To assess extent of similarity between the synonyms under consideration and the candidate word, list of their contexts have been taken into consideration. The work makes use of various corpora for extracting contexts.

Chapter IV: Dynamic Entity Resolution: This chapter covers the detailed discussion on the proposed and implemented work to generate a rich set of entity synonyms for the commonly used entities using web data, web log and anchor text. An index has also been created to assess the quality of the created synonym. Obtained results have been compared with the existing techniques.

Chapter V: Concept Resolution for Focused and Enriched Web Information Retrieval: This chapter proposes and implements an algorithm for concept resolution using *PROBASE*, a huge taxonomy on worldly knowledge created by Microsoft, in combination with users' statistics resulting in focused and enriched outcomes. The results so obtained have been compared with the outputs of existing search engines such as Google, Bing and Yahoo.

Chapter VI: Conclusion and Future Scope: This chapter concludes the work and provides a description of potential future work in the area under consideration.
